This book is ambitious in scope, overwhelming in erudition, and challenging in thesis. The first hundred pages, constituting Part One, state the theme: the categories conventionally used in classifying contemporary economic systems are inaccurate and provoke discord among nations by their mutual exclusiveness. Such supposedly extreme systems as those represented today by the United States and the Soviet Union are in fact constantly in flux and are both tending towards some mean position between them, such as that occupied by Great Britain. In short, according to Professor Surányi-Unger, the outmoded static concept of rigid differences in kind must give way to the more fluid concept of ever-changing differences of degree.

Part Two (about twice the length of Part One) analyzes the *social* elements which today at once differentiate and fail to differentiate the "American sphere" from the "Soviet sphere." This section relies heavily on history, philosophy, anthropology, and allied disciplines. The point stressed here as elsewhere is the fundamental and growing *rapprochement* between "West" and (Soviet) "East."

The third part, and second half, of the volume discusses the *economic*

element in contemporary systems. In so far as systems may be identified by their economic characteristics, the chief criterion is the relative amounts of collectivization and private enterprise. The reader will find in these latter chapters most of the material customary in textbooks in this field, but only by way of illustrating the author's theses regarding the distinctions, and lack thereof, between the Soviet and non-Soviet worlds. The theme of dynamic transmutation of economic systems is stressed for a third time. The author repeats here the argument of his earlier volume,[1] including his questionable idea that "collectivization" may be treated by the indifference curve technique as a "good" opposed to "reprivatization." Indeed, this volume as a whole may be viewed as a restatement and expansion of the earlier volume, recapitulating it verbatim in places. (*Cf.* p. 293 of the new with p. 15 of the earlier volume.)

The book suffers from confusion as to aim. No work can successfully be simultaneously an original treatise and a beginner's guidebook. To mention just one difficulty in this connection, the language of this book is not infrequently too esoteric for normal readability and is certainly beyond the college student. Not only should a textbook not double as a treatise, but no scholarly publication should be a tract, and this book at times harangues too much.

The most constructive aspect of the book is its experiment in polysynthesis. There can be no doubt that a "general" economics which can deal with new twentieth-century forms of economy as well as with traditional laissez-faire capitalism must combine the mathematical formalism of modern analytical theory with knowledge from the general corpus of social science.

Unfortunately, the author's vast coverage is at the cost of some error. For example, he misconceives the nature of both Platonic and medieval philosophy (p. 134), misappraises the kolkhozi (pp. 30 and 394-96), and oversimplifies and distorts Marx (p. 136). His gravest deficiency is that he founds his system upon an extreme nominalism which he cannot sustain and which leads him into profound pitfalls. His denial of the existence of distinctive species or categories implies the impossibility of man's power to generalize—a power upon which all human knowledge rests. It also belies our common-sense realization that fascism, say, is in truth a distinctive system. Its practical consequences are most dangerous, for it counsels a do-nothing policy in the face of evil on the grounds that the evil (1) is not there (differences do not exist) and (2) will go away (differences of degree dynamically disappear). Moreover, despite his denial, he finds himself forced to erect classificatory systems of his own based on questionable distinctions, such as materialistic and nonmaterialistic, primary and secondary, distributive and equalitarian economies.

A system, whatever its merits, is not likely to convince if it even merely superficially seems to be obscure and contradictory.

National Income and Social Accounting

Veränderungen der Einkommensverteilung in England, 1938-1948. By ERWIN GERBER. (Bern: Rösch, Vogt und Co. 1952. Pp. vii, 152. 16 sw. fr.)

A study from abroad of economic change in a country is frequently of interest because distance results in better perspective and detachment from partisan issues or because a comparison with developments in the author's own country enriches our knowledge of comparative economics. The present study has none of these merits.

Dr. Gerber's study on changes in the distribution of personal income in the United Kingdom falls into three parts. In the first chapter, changes between 1938 and 1948 are described and particular attention is paid to factors which have caused an increase in the share of wage income in the total. The second chapter deals with the impact of taxation on the size distribution of disposable income. In the third chapter, changes in real personal income are discussed. The main findings on the extent of the levelling process and on the effects of taxation and of differences in the change of the cost of living, summarized in a concluding chapter, are broadly in agreement with those reached by British students.[1]

The study is organized around some 50 tables drawn from a variety of British publications ranging from the official White Papers on National Income to the Conservative Campaign Guide. The author's use of source material is, however, less critical and imaginative than in the recent journal articles by Barna, Brown, Reddaway, Rhodes, Sears and Wallis (to which Gerber, however, makes no reference).

Gerber's study contains no material that would not be known to students of the British economy, although it will provide the continental reader with a wealth of information on such subjects as the United Kingdom income tax structure (including sample computations of tax returns), the computation of Laspeyre's index or the Organization for European Economic Co-operation recommendations for an investment program for the United Kingdom. A good part of the text consists, indeed, of brief summaries of articles which have appeared in recent years in the London *Economist*, including the well-known series on the Age of Inflation, and of various documents, such as the Labour government's "Statement on Personal Incomes, Costs and Prices" of February 1948.

The author's endeavor to give the study a logical structure by subdividing a 150-page monograph into fifty sections with separate headings is defeated by his wrestling with definitions. Indeed, the struggle begins on page 1, where in a footnote he tries to clear up the confusion arising from the continental use of the terms Great Britain and England to denote the territory of the United Kingdom (but thereafter proceeding to use these three terms indiscriminately). This reviewer wonders whether the problems of exposition would not have been simplified if the author had avoided using such cumbersome definitions as the following one for taxes, at the beginning of Chapter 2,

[1] See, for instance, D. Sears' article in the October 1949 *Bulletin of the Oxford Institute of Statistics.*

taken from Amonn's textbook: "A compulsory payment levied by a government unit from private economic units belonging to it, by virtue of the fact of their belonging to this unit, 'belonging' being defined not in a political or territorial, but in an economic sense, namely as belonging to the economy of the Government unit."

In many cases when Gerber's exposition reaches a point where some broader and provocative analysis could have been attempted, he rules the problem to be "outside the scope of our study." Yet the study is overloaded with material only indirectly related to the subject and used to only a very limited extent in subsequent discussion. Thus, after a lengthy summary of the well-known article by Mary J. Bowman,[2] illustrated by charts in which the original American data are replaced by U.K. income distributions, the author remarks that the preceding pages should have simply shown the potentialities of graphical analysis.

GEORGE GARVY

Federal Reserve Bank of New York

Business Fluctuations; Prices

The American Economy in 1960. By GERHARD COLM, assisted by MARILYN YOUNG. Planning pamph. no. 81. (Washington: National Planning Assoc. 1952. Pp. ix, 166. $2.00.)

The Sustaining Economic Forces Ahead. Materials prepared for the Joint Committee on the Economic Report by the Committee staff. (Washington: Supt. Docs. 1952. Pp. viii, 70.)

Markets after the Defense Expansion. A report prepared by the staff of the Office of Business Economics, Dept. of Commerce. (Washington: Supt. Docs. 1952. Pp. vi, 90. 55 c.)

These three pamphlets, or monographs, attempt to present a factual and analytical basis for judgment about future levels of economic activity. All are written for the purpose, which is more or less explicitly stated, of allaying the fears of a major recession or depression that have gained dominance among economic analysts. In the words of Colm, there is "some validity and a good deal of error" in such views (p. 69).

Attempts to counter public fears with official reassurances have, in the reviewer's opinion, little merit, because they carry the disturbing implication that they would never have been made if the situation were really secure. In contrast to the outpouring of such "reassuring" speeches and press releases from Washington since the Russian "peace offensive," these reports really present the kind of evidence that permits a rational appraisal of prospects.

All three deny that any specific forecast is intended. The objective is rather to present projections, based on stated assumptions, as guides to government and business in planning for prosperity without inflation in the years ahead. There is substantial unanimity that although the danger of a decline

[2] "A Graphical Analysis of Personal Income Distribution in the United States," this *Review*, September 1945.

exists, the evidence that it will be serious, or even occur at all, is not conclusive. To quote the Commerce Department, 1955 may be expected to "provide a serious test of strength of the economy." But, "we cannot conclude that a business recession will or will not occur, sometime, or any particular time, during the next few years" (p. 3).

The Sustaining Economic Forces Ahead was the earliest of the three in timing of analysis and in date of publication. Originally undertaken when the pessimism of early 1952 was at its height, it represents a rather straightforward attempt to refute prevalent arguments that a serious decline was in the offing. It deals with the entire period from 1952 to 1960 in terms of the investment and other goods that would be needed to maintain minimum living and production standards in a growing, healthy economy.

It may at times strain a little in making its point—for example, in relying on the projection of geometric trend lines—but even discounted for possible exaggeration, the estimates are large enough to call in question the more pessimistic predictions that are currently in circulation. The independence of thought and judgment underlying this work is illustrated by the adoption of population estimates in the higher part of the range of probabilities projected by the Census Bureau, with a challenge to the population "experts," that they "assume rather unrealistically that by 1955 the birth rate will have fallen to the depression low" (p. 12).

The American Economy in 1960 jumps the intervening years to analyze the possibilities of achieving and maintaining full employment after the defense build-up is complete and military spending drops back from a peak of $60 billion to a maintenance rate of $40 billion. The analysis is carried out in terms of a series of models, all of which assume an international situation much like the present and a gross national product of $425 billion in 1951 prices (based on armed forces of 3.5 million and a civilian labor force of 69 million with 4 per cent unemployed).

The method of constructing the models is described in some detail. Each assumes a different way of arriving at the $425 billion total—essentially by assuming that the deflationary gap left by the decline in military expenditures will be filled by compensating changes in one or another of the major sectors of the economy, as represented by consumer, business, international, and government accounts. One by one, all of these partial models are rejected, leading to an "adjusted" model in which each of the sectors makes a more moderate contribution to the projected level of activity.

Colm displays a mastery of the method based on long experience, having been associated with its development from the beginning. Nevertheless, his results illustrate again that model building can produce almost any desired result. A combination model that requires only limited contributions from various sectors is seemingly more realistic than one that requires an extreme contribution from one sector; but the combined result is dependent upon a conjuncture of adjustments that is not necessarily more probable than a single large adjustment. Perhaps the biggest question mark lies in the consumer account. The saving rate is assumed to drop from the recent 8 per cent of disposable income to 5.4 per cent—equivalent to that experienced in the

somewhat abnormal years 1948 and 1950. Colm's statement that this implies the "same situation—high positive saving, and heavy purchases of consumer durables, supported by an increasing level of outstanding consumer credit" (p. 55)—is not entirely reassuring.

Colm puts his models to the best use to illustrate the "policy adjustments" needed to promote high level stability. Among the policies recommended are low prices, low interest rates, low taxes, and borrowing to finance some government investments but none of its current operating expenses. In discussing these policy adjustments, many theoretical points are developed. With reference to the government budget, for example, it is pointed out that "a balanced cash budget on a high level might be inflationary while an attempt to balance the budget on a lower level may be deflationary" (p. 87). There is much of interest to the general economist in both the body and the appendixes of this report.

Markets After the Defense Expansion is specifically aimed at informing "the business community on factors affecting the level of civilian demand after the present defense program has reached its peak" (title page). The bulk of the pamphlet is devoted to a discussion of the current position of the major segments of the gross national product and prospective changes that might be expected in each between 1952 and 1955. At the end, it presents "a high-level market pattern" for 1955—a model, of the Colm variety, based on the assumption that the economy will continue to operate at a high rate—and offers some suggestions for applying this market pattern to the problems of the individual business concern.

It presents the material needed for making a short-term forecast without actually organizing it into an over-all forecast. The techniques used in analyzing the segments vary considerably. To illustrate, the chapter on "Business Intentions to Invest" begins by presenting the results of two surveys of the future capital outlays planned by business concerns; it immediately supplements these with analytical material taking account of historical trends and the magnitude of current investment in relation to capacity and profits; and it then goes on to discuss inventory fluctuations, the availability of financing, and the degree of market satisfaction for other forms of investment, such as farm, institutional, and residential construction. At various points, the resources of other organizations and agencies are drawn upon to round out the Department's own work. Altogether, it is the best analytical summary of factors in the business outlook published to date.

All three of these publications place considerable emphasis on the continuing growth of the economy as a factor limiting the extent and duration of cyclical declines. They also emphasize the extent to which such declines will be mitigated by the automatic stabilizers that have been built into the economy—mainly, flexible taxes, unemployment compensation, old age pensions, farm price supports, and insurance of bank deposits. Recognizing that the quantitative effects of these factors will be limited, however, they fall back on the Employment Act of 1946 as an indication that vigorous action will be taken by the government if any decline should threaten serious unemployment.

The reader whose primary interest is practical and short-run will find

Markets After the Defense Expansion well worth the reading. Those whose interest leans more to theoretical considerations and the longer-run will find *The American Economy in 1960* rewarding. These two contain most, though not all, that is of lasting value in *The Sustaining Economic Forces Ahead.* Together, they disclose the strengths and weaknesses of an economy facing a transition at the peak of an armaments boom and the problems involved in keeping it prosperous in the future.

V LEWIS BASSIE

University of Illinois

Economic Stabilization: Objectives, Rules, and Mechanisms. By WALTER P. EGLE. (Princeton: Princeton Univ. Press, for the Univ. of Cincinnati. 1952. Pp. xii, 264.)

Taking his cue from the late Henry Simons, Professor Egle has set himself the task of impressing all those interested in stabilization policy with the need for binding goals—for firm government commitment to clearly defined floors and ceilings of aggregate economic activity. However, Egle would aim primarily at the stabilization of employment and income and only secondarily, prices. Emphatically rejecting as inadequate reliance on automatic stabilizers, he has also placed the emphasis on the need for discretionary, countercyclical variation in federal expenditures and tax *rates.* If we add his expectation (like that of Simons) that his scheme will ultimately become self-enforcing, we have in a nutshell Egle's central theme.

To the professional economist, the book under review is likely to appear as a restatement of familiar ideas. Such a work is not without merit, provided it offers a thorough examination and scholarly appraisal of issues and alternative proposals. Unfortunately, these traits are lacking in the present book. Egle has been content to raise a lot of old (though still important) questions, but after a few cursory remarks, drop them again without having shed much new light. The book rather resembles a (good) manual for policy-makers and administrators. In fact, it should be made required reading for these groups, as well as for all congressmen and members of the business community at all interested in stabilization problems.

The first two parts of the book are largely an examination of the adequacy of variously proposed built-in stabilizers. In the first part, Egle deals with what he calls "fixed schemes," which are really automatic-stabilizers proper (corporate and personal income taxes, underemployment compensation, etc.). The second part deals with what he calls "flexible schemes," *i.e.,* programs which permit discretionary action circumscribed by a set of legislative rules, as well as various kinds of "tripping" devices for effecting automatic changes in tax rates and expenditures. After brief discussion, the first group is rejected on the well-known grounds that built-in stabilizers can provide only retarding influences on income movements. Except for the "stable money" people, most readers will find little to dispute in this discussion, other than the elliptic nature of much of it, particularly the analytical portions.

There is more to quarrel with in Egle's rejection of the so-called "flexible"

stabilizers. He displays too strong a tendency to dismiss proposals out of hand. Thus in rejecting the method of heavy public works, he raises the old arguments about their lengthy planning, inception, and termination periods. No recognition is given to the important work of Benjamin Higgins,[1] who, after detailed empirical study of the problem, has indicated that a good deal of flexibility can, in fact, be incorporated into public works programs. Since public works programming offers such a potentially important rôle in compensatory fiscal policy, Egle should, if he disagrees with Higgins' ideas, have dealt with them in some detail in a book of this kind.

Automatically varying tax rates are summarily rejected on the vague grounds of "annoyance" to taxpayers, the administrative problems posed to government officials, and the possibility of confusion to businessmen brought about by varying tax schedules. However, as to this last difficulty, it would appear that Egle himself is confusing certainty with constancy of variables in decision functions. As long as rate changes occur in a predictable manner, known beforehand to businessmen (a condition implicit in such proposals), confusion from this source will be at a minimum. On this point alone, it might be argued that automatic variation in tax schedules is better than discretionary variation, since the former is at least predictable. At a more general level, it is to be observed that most of the problems posed by Egle in this connection would apply with equal force in a discretionary scheme of things. The major, and perhaps decisive, exception to this statement lies in the implicit assumption underlying the automatic program that there is something uniform about the way in which the strength of cyclical forces operates, not only from cycle to cycle, but among the different phases of each cycle.

However, as Egle notes, "the purpose of such rules is not to reduce the handling of such controls to sheer routine but to make certain that the control will be used to fight swings" (p. 86). Advocacy of this type of automatic program has stemmed largely from a recognition of the need to do away with the woeful lags inherent in the present legislative scheme of things, and at the same time, from a recognition of the wisdom of presenting such proposals in as palatable a manner as possible to a Congress jealous of its prerogatives in tax and appropriation matters. For one who gives so much attention to such "practical" considerations, Egle is surprisingly harsh on proposals of this type.

Part III, the core of this study, concerns itself with an analysis of the theory and application of the "method of binding targets." "The principal source of weakness in past stabilizing efforts has been the absence of clearly formulated (objectives) and powers on the part of authorities entrusted with cycle control" (p. 97). The means to achieve the end must be adequate, which means strong discretionary powers to vary budgetary outlays and tax rates to the required extent. "The ultimate purpose of the binding norm is to establish public confidence in future markets and job opportunities (in the hope that) producers and consumers will behave so as to simplify greatly the task of the stabilizing authorities" (p. 98).

"Objectives should be stated in terms of a binding floor and ceiling making

[1] *Public Investment and Full Employment* (Montreal, 1946).

for a liberal margin of fluctuations" (p. 97). A floor of 5 million unemployed is suggested to avoid the problem of differentiating voluntary from involuntary unemployed and to avert the possibility that too high an employment floor might give rise to wasteful "quasi-doles." Fears of the latter seem at odds with Egle's ideas of a carefully conceived program. And 5 million unemployed seems rather high in the present social context. Officials were decidedly fretful in 1949 when unemployment rose to some 3 million.

Problems of fixing a ceiling are rather formidable, too. Egle is inclined to think in terms of a *price* ceiling, because inflationary price movements are ordinarily ineffective in inducing expansion of output and employment. However, the degree of inflation should be specified. One could make a pretty fair argument that some inflation (say, about 2 per cent a year) is a good thing for investment outlays in a free-enterprise economy faced with possible saving-investment problems. If there is anything to the Kondratieff thesis of long waves of exhilaration and depression or stagnation, one might point to the long periods of differential price movements as offering some corroboration of this suggestion. Moreover, there are such problems as rising prices long before full employment is reached and the ever-ticklish possibility of converting upswings to downswings. Some inflation might well be tolerated to avoid the latter problem.

The principal thesis of the final part of the book is the need to back up strong monetary-fiscal tools with such direct controls as qualitative credit and even price and wage controls, as a means of coping with serious sectoral dislocations or maladjustments. Egle places particular stress on these controls during the "launching period" of his program, when the problems of rigidities and inflexibilities are likely to be particularly acute. To deal with the latter, strong action toward "competitive reform" is urged. While not wishing to dispute the merits of such reforms on other grounds, this reviewer feels that Egle handles the problem of the relationship of monopoly (or oligopoly) to business fluctuations much too glibly.

At the outset of this book there is a discussion of the relationships between the problems of stagnation and cyclical instability, which leaves much to be desired. In particular, Egle is too prone to dismiss the stagnation thesis without sufficient appraisal of its merits or weaknesses. Instead, there is a facile tendency to toss off the problem as a product of "monopolistic restrictions and undue concern with security." As a result, Egle finds "particularly aggravating" the various suggestions for stimulating private investment and lending activities, because such programs might generate unprecedented business fluctuations. This position, of course, begs the central question of his entire discussion, *viz.*, whether future secular growth of the U.S. economy will be characterized by underlying stagnation or inflationary tendencies. Correct emphasis in the area of fiscal and monetary policy requires some evaluation of long-run trends, a (thankless) task to which Egle should have addressed himself. After all, if a tendency toward chronic underemployment should, in fact, manifest itself, there is the possibility that his book would be quickly relegated to the History of Economic Thought.

D. HAMBERG

Readings in Business Cycles and National Income. By ALVIN H. HANSEN and RICHARD V. CLEMENCE, *editors.* (New York: W. W. Norton. 1953. Pp. xi, 588. $3.95.)

This collection of readings "is intended primarily for the use of undergraduate students" for the purpose of gaining "a firsthand acquaintance with at least some portion of the literature of their subject." The 37 selections are arranged in seven groups: Historical Episodes (4 selections); Business-Cycle Theories (11); Economic Dynamics (6); Econometrics (6); International and Interregional Aspects (3); Long Cycles (2); and Cycle Policy (5). The readings are reprinted in full, and the editors have prefaced each selection with brief comments to introduce the reader to the author and his work. The "Business Cycles" of the title is apposite in that the readings deal primarily with fluctuations, while the "National Income" portion of the title is accurate in the sense that most of the articles analyze cycles on the aggregative level. In addition, several of the articles in the Economic Dynamics and Cycle Policy sections are concerned in part with the conditions for steady growth of national income over time.

The collection will be of greatest value to those instructors who teach business cycles primarily as a course in cycle theory—or, more accurately, in cycle theories. Part Two, on business cycle theories, has a strong history-of-doctrine flavor: the authors of the selections are J. S. Mill, Jevons, Alfred and M. P. Marshall, Pigou, Spiethoff, Cassel, Aftalion, Hawtrey, Mitchell, Robertson, and Kahn. The frontiers of contemporary thought are represented by the readings in Parts Three and Four, on economic dynamics and econometrics. The selections in Part Three deal with the neo-Keynesian models of Harrod, Hicks, and Metzler. It is something of a surprise to discover that only one of the six selections in the econometrics group (Einarsen's summary of his work on reinvestment cycles) is devoted to statistical work with a theoretical model. Tinbergen's "Critical Remarks on Some Business Cycle Theories" reports some of the results of his investigations, but does not reproduce his models. A third article in the group, Kaldor's "A Model of the Trade Cycle," really belongs in Part Three. The remaining articles in Part Four are concerned with methodological problems, and include the Keynes-Tinbergen controversy on statistical business cycle research.

It is axiomatic that the editors of a collection of this nature cannot please everyone. In the present instance the editors have done well what they set out to do. Given their framework, the quality of the selections is high, and a reasonable balance of differing points of view is maintained. In this context, the reviewer really missed only two readings. Keynes' "Notes on the Trade Cycle" from the *General Theory* might well have appeared in Part Two, and Schumpeter's 1935 article from *The Review of Economic Statistics* in Part Two or Three. (The latter, however, is reprinted in the American Economic Association's *Readings in Business Cycle Theory.*) On the other hand, it was a pleasure to discover that materials on international and interregional aspects of cycles and Garvy's excellent article on Kondratieff's theory of long cycles had been at last made easily available for student use.

The reviewer was somewhat disturbed by the comparative underrepresentation of the points of view of those scholars who believe that research in the field of business cycles should combine theoretical, statistical, and historical analysis. Thus Metzler's review of Burns and Mitchell's *Measuring Business Cycles,* which is included in the collection, provides a brief summary of "the National Bureau technique" of business cycle research together with a critique of the approach, but no defense of the approach appears in the volume, nor is there anywhere an example of the use of the method. The first deficiency could have been remedied by including, for example, Part V of Chapter I from Mitchell's 1927 *Business Cycles,* and the second, by reprinting Abramovitz' preliminary summary of his investigation of the rôle of inventories in business cycles, which appeared as National Bureau of Economic Research Occasional Paper 26. Again, although analyses of four historical episodes appear as Part One of the volume, no methodological discussion of the historical approach—such as that presented in Gordon's paper in the 1949 *Papers and Proceedings* of the American Economic Association—has been provided. As a final example, it may be noted that none of the several discussions of Harrod's and Hick's cycle models which appear in Part Three (with the possible exception of Wright's article) is unsympathetic to the few-variable, *a priori,* aggregative approach which they exemplify. The substitution or addition of A. F. Burns' "Hicks and the Real Cycle" (*Journal of Political Economy,* February 1952) would have improved the balance of this section. It is obvious that modifications of the type suggested in this paragraph would imply either a substantial increase in the length of the book or a sacrifice of readings—probably from Part Two—which the editors evidently felt were of greater importance for the purposes of undergraduate instruction. Nonetheless, the suggested changes would have increased the already substantial value of the book to those instructors who hold the opposing view.

Hansen appears in the volume only as joint-editor. It is unfortunate that editorial modesty has prevented the inclusion of some selection representative of his thought. His restraint is the more remarkable in that Simons' polemical review of *Fiscal Policy and Business Cycles* appears in the Cycle Policy section. The remaining readings on cycle policy include articles by Kaldor and Slichter, the committee report by the American Economic Association on the problem of economic instability, and a review of the committee report by Smithies.

The theoretical selections in the volume are complementary to those in the American Economic Association's *Readings in Business Cycle Theory.* Only one article is common to both books. The present collection is broader in scope than the earlier volume—including as it does readings on historical episodes, regional aspects of cycles, and econometrics—and covers more recent theoretical developments. It will find a place on the shelves of graduate as well as undergraduate students.

BERT G. HICKMAN

Northwestern University

Money and Banking; Short-Term Credit; Consumer Finance

A Study of Moneyflows in the United States. By MORRIS A. COPELAND. (New York: National Bureau of Economic Research. 1952. Pp. xxxii, 338, A235. $7.50.)

In his introduction, Winfield Riefler gives us some background information which is important to an understanding of this unusual book. "Years went into the creation of the grand design of this study. . . . Those of us who have been privileged to know Morris Copeland through his lifetime will find that every page evokes echoes that reach long into the past—echoes from his earlier absorption with accounting . . . echoes from his sojourn at the Federal Reserve Board, where he undertook to fill in the equation of exchange from empirically derived data; and echoes from his days as Executive Secretary of the Central Statistical Board where he operated so effectively to improve the quality, the comparability and the coverage of American economic statistics. . . . There are other echoes also, more personal ones, of Copeland's preoccupation with theoretical formulations and his insistence that they be subjected to empirical verification" (p. ix).

The product of this rich and varied experience, of these years of theoretical probing and factual research is beyond any question an impressive document. Readers will find much to interest and delight them: new statistical material, sharp analysis of accounting detail, fresh discussion of familiar theoretical problems. But they will also find, I think, that this is in some ways a puzzling as well as an impressive book.

It should be pointed out, to begin with, that the author undertakes to do four different things in this study: to construct a detailed set of moneyflows accounts; to compile statistical estimates of the moneyflows thus specified for the seven years 1936-42; to examine the basic concepts of a money economy; to formulate a theory of fluctuations for use in interpreting the statistical findings.

Moneyflows are payments—or receipts, depending on which way you look at them—made by one "transactor" to another. Four major types of transaction are included in the moneyflows system, or "main money circuit," as the author calls it: final product transactions—these are payments for and "primary" distributive shares arising from the goods and services that make up the Gross National Product;[1] nonfinal product transactions; transfers, both public and private; and moneyflows through financial channels, *i.e.*, transactions which "involve a change in the receivables of one transactor and the payables of the other . . ." (p. 57). As a by-product of his work on financial moneyflows the author also gives us estimates of the balances from which they are derived.

The transactors who engage in these various types of dealings with each other are divided into eleven groups: households, industrial (in the broad sense) corporations, farms, unincorporated industrial enterprises, the federal

[1] Except for imputed items, which are excluded from the moneyflows system. There are also differences in timing as a result of the fact that moneyflows are measured on a cash and GNP on an accrual basis.

government, state and local governments, banks and U. S. monetary funds, life insurance companies, other insurance carriers, security and realty firms, and the rest of the world. Intragroup transactions (*e.g.*, payments by households to other households) are included in the totals[2] but play little part in the subsequent theoretical analysis. In deciding how to divide the economy into sectors the author seems to have been guided largely by statistical considerations: "Conventions and to some extent statutes have provided a basis for handling the problems of classifying transactors. In dividing the economy into sectors, we shall follow in general the Standard Industrial Classification, and, in deciding when we have one transactor and when several, we shall for the most part take our cue from federal corporate income tax returns" (p. 38).

While the total of moneyflows is larger than Gross National Product, it falls short of the total of all transactions in which transfers of money are involved. "The main money circuit excludes a large volume of money payment transactions that are mere 'whirlpools at the side of the main flow': money changer transactions, agency transactions, and financial turnover transactions (*e.g.*, the repayment of a loan financed by an offsetting renewal). In 1942 45-50% of debits to individual accounts represented such mere whirlpools, in 1937 about 60 percent" (p. xxiii).

It is unfortunately impossible in a summary like this to give an adequate idea of how much skillful, painstaking analysis of detailed accounting problems the author performs in the process of working out the full specifications for the system of moneyflows accounts. This work makes up a large—and, for readers who are interested in the technical problems of social accounting, or who merely enjoy refined accounting analysis for its own sake, very rewarding—part of the book. Its usefulness is broadened by frequent comparison of the way items are handled in the moneyflows and in the national income accounts; these sections of the book can, in fact, be highly recommended to anyone who wants to improve his understanding of the technical aspects of national income accounting.

Construction of the detailed scheme of moneyflows accounts and of the statistical estimates to fit them would have been a big achievement by itself. But the author has not been satisfied to rest on his laurels as accountant and statistician. He has gone on to "re-examine" the conceptual framework of the money economy, and to erect on the foundation thus prepared a theory of how fluctuations in moneyflows, and hence in general economic activity, are initiated and amplified.

His examination of the conceptual framework covers such questions as: What is money? What functions does it perform? How is the quantity of money increased or decreased? What is the proper concept of "flow" as applied to money? The answers he gives are much the same as those of other contemporary monetary theorists, *e.g.*, for society as a whole money performs a scorekeeping, for the individual a cushioning function; the money supply consists chiefly of the currency and deposit liabilities of the banking system;

[2] Except for the banking sector, for which a consolidated statement is presented, and for some netting of financial transactions (see p. 191).

changes in the quantity of money are the result of expansion or contraction of bank assets and liabilities, and can hence be influenced, though not controlled, by the banking system; the way money "flows" is more like electricity than water; *i.e.*, the "process of payment is instantaneous in the sense that no paying transactor loses title to a penny of cash until title is acquired by the payee. . . ." (p. 236). Money is thus never "in circulation" as water is (*i.e.*, actually "on its way," in the pipes or other conduits from one "reservoir" or "pumping station" to another).

Readers may be somewhat puzzled as to why Copeland devotes as much attention as he does to such questions as these. To find the explanation we must, I think, recall what Riefler says in the Introduction about the years that went into the "creation of the grand design of this study" and about the "echoes . . . of Copeland's preoccupation with theoretical formulations," echoes that "reach long into the past." Much of that preoccupation was no doubt with the shortcomings of the quantity theory as it was commonly formulated in this country in the late 'twenties and early 'thirties. Having started to work out the necessary revisions before the revolutionary developments of the mid-'thirties had occurred, Copeland apparently continued to develop his ideas independently of what was happening in the main current of monetary and income theory, coming in the end to conclusions which, at least as to the basic concepts mentioned above, are much the same as those that are now generally accepted.

This hypothesis receives strong support from the first verse of the "Alternative Statement" of his views which the author gives us at the end of the book (p. 322):

> The estimates arrayed themselves in columns and in rows;
> They showed the cash each sector held; they showed its moneyflows.
> "The time has come," the Walrus said, "To talk about inflation,
> If all the cash outside the banks is cash in circulation,
> Do you suppose that moneyflows increase as cash increases?"
> "I wonder," said the Carpenter, "Let's take this thing to pieces."

Working things out independently frequently has its advantages. But there are dangers too. These are clearly illustrated by the author's attempt to construct a theory of fluctuations. The essential points of this theory are summarized by the author as follows (pp. 259-60):

> It is convenient to think of transactors in terms of a three-party system, the three parties being called respectively bulls, bears, and sheep. Bulls are transactors who dishoard to increase their spending . . . Bears are those who stint and hoard . . . All other transactors are sheep. Ordinarily sheep will be increasing their expenditures so slowly that they hoard when the volume of moneyflows is expanding . . . (and vice versa when it is contracting) . . . To the question, How do increases and decreases in moneyflows take place? we answer then: Mainly and immediately through the decisions of individual transactors about their ordinary expenditures . . .
>
> Our hypothesis implies that changes in active cash balances are a consequence of and a necessary condition to changes in moneyflows, not a cause. The increased spending of a bull results from a decision by the

> bull. The decision is made possible by his ability to dishoard. His dishoarding may take the form of drawing down his cash balance or borrowing from or selling securities to banks. The hoarding of other transactors may take the form of increased holdings of cash or may take other forms.
>
> Much of the time the question whether moneyflows will increase or decrease is determined by whether the bulls (active dishoarders) or the bears (active hoarders) predominate. But the bulls and the bears alone do not fix the entire amount of the increase or decrease. When a cyclical increase gets under way it tends to become cumulative, *i.e.*, sheep may keep the expansion in their ordinary expenditures nearly abreast of the expansion in their ordinary receipts. On the downswing too we must allow for the influence of the sheep. Contraction of moneyflows is perhaps even more likely to be strongly cumulative than expansion.

There is, of course, nothing wrong with this as far as it goes. It is, in fact, quite similar to modern, "Keynesian,"[3] income theory. The big difference is that Copeland stops short of any inquiry into motives. He does not even ask why bulls—or bears or sheep—act as they do. In Keynesian theory, on the other hand, motivation plays a key rôle. Keynesians suggest, for instance, that one of the major reasons for a transactor's being a bull is that he sees an opportunity to make a profit by buying new capital goods. They accordingly treat investors, *i.e.*, people who are in a position to make decisions about buying capital goods, as a separate group of transactors whose actions are worth special study. There is, of course, nothing new or original about this assumption. It is a familiar feature of classical and neoclassical theory. But one of the great strengths of Keynesian theory is its willingness to draw freely on its classical heritage. By linking "bullish" behavior, for instance, to decisions about the purchase of capital goods it ties the theory of fluctuations in with the theory of investment, which had already been developed to a significant extent by earlier generations of economists and to which further important contributions have been made by Hansen, Samuelson, and others in recent years.

Copeland seems to miss this point completely. The only differences he mentions in comparing Keynesian theory with his own are differences in (1) the "level of aggregateness," (2) the use of the "accrual" as opposed to the "moneyflows perspective" (p. 250), and (3) the fact that saving and investment are concerned with the "ultimate sources of capital funds—households and quasi-households—and the ultimate uses—for additions to tangible wealth . . . ," while the financial moneyflows account "aims to reveal the immediate suppliers . . . and the immediate takers of funds" (p. 185). But surely these are merely accounting technicalities. Keynesian theory could easily be restated in terms of the moneyflows perspective and the immediate sources and takers of funds. And it has already proved itself admirably suited to development toward lower levels of aggregateness.

[3] As to the relation between modern and Keynesian in this context *cf.* A. G. Hart, *Money, Debt, and Economic Activity* (New York, 1948). "This book is neither Keynesian, anti-Keynesian, nor on the fence. On the other hand, it is definitely not *pre-*

Why is Copeland reluctant to inquire into motives? We cannot be entirely sure of the answer. But there are some clues which may be significant. One of these is a statement in the last chapter concerning "habit patterns;" "Our analysis has made little use of habit patterns. What can be done with habit patterns when observations are confined to seven years is necessarily limited" (p. 333). One is tempted to turn this statement around and say: "What can be done with seven years (or any other period) when observations bear no relation to habit patterns is even more limited." Like the Institutionalists in economics, and the Behaviorists in psychology, the author apparently hopes to derive his theory from his observations. But without any theory to begin with, without any "habit patterns" in mind to test, how can he know what things to observe? If, for example, we are to learn anything about the causes of economic fluctuations from statistics of moneyflows and loanfund balances we must divide transactors into groups which have some relation to the phenomena we are studying. We are not likely to have much success if we adopt any basis for classification that happens to come to hand; say, by age groups, or by degree of consistency in voting record, or by religious affiliation, important though these groupings are for other purposes. Perhaps if we went on indefinitely testing systems of classification we should eventually stumble on a significant one. But that of course is quite impracticable. We need to use everything we know about the way people behave to set up categories which at least have a good chance of turning out to be significant. Only in this way can we hope to narrow the range of possibilities enough to make the problem manageable.

Copeland sets up his scheme of classification, *i.e.*, his eleven transactor groups, without any explicit reference to his theory of fluctuations. He notes in passing that: "To the extent that a transactor group includes members of all three parties at the same time we may have trouble . . ." (p. 260). But apparently he sees no connection between this danger and the way in which the transactor groups were chosen to begin with. His remedy is simply to increase the number of groups, still without inquiring into the motives they might have for behaving in one way rather than another in relation to fluctuations in economic activity.

Actually, Copeland's practice is better than his theory. Although he does not explicitly relate his transactor groupings to his three-party theory of the bulls, the bears, and the sheep, it turns out that there is a certain amount of correspondence between the two. This correspondence is not nearly as great, however, as it could be. By rearranging transactor groups and reclassifying types of transactions in ways that are appropriate to test various hypotheses, other investigators will, no doubt, be able to make more use of the wealth of material on moneyflows and loan fund balances we have here. Copeland might have gone further in this direction if he had not been handicapped by his inhibitions against using "subjective" theory. This should not, however, obscure our recognition of the important job of statistical spade work he has done, work which will facilitate the efforts of all future workers in this field.

ALAN R. SWEEZY

California Institute of Technology

La Federal Reserve et les difficultés monétaires d'après guerre 1945-1950. By MARCEL RIST. (Paris: Librairie Armand Colin. 1952. Pp. xiii, 365. 1100 fr.)

In the literature dealing with the rediscovery of monetary policy following the oblivion of the 'thirties and the 'forties, this book on the Federal Reserve System and the postwar monetary difficulties has a special place. Written by Marcel Rist, the grandson of Charles Rist, the dean of the French economists, the book has the distinctive French quality of making clear an essentially complex matter. True, the American reader acquainted with the Douglas and Patman committees' material and with the writings of Chandler, Goldenweiser, and Roosa will find little that is new in Rist's account of the postwar monetary developments and policies in the United States. Nevertheless, he will greatly enjoy the skill with which the author handles the sequence of events and the course of the monetary policy debate; and he will be glad to know that those French and other European readers who do not have access to American sources can find in Rist's book a fair and comprehensive interpretation of the postwar monetary history of the United States.

For the American reader, the chief interest in the book rests in the fresh look that the author takes at the postwar American experience. Rist first endeavors to appraise this experience from the viewpoint of monetary theory, more particularly in the light of the Hicks-Hansen liquidity function model, which he has somewhat rewritten and newly qualified in order to make it more realistic; the upshot is quite interesting even though it adds little, I believe, to the conclusions arrived at otherwise. Rist then sets forth the American experience within the general framework of central banking trends as these have developed during the postwar years. This is the most valuable part of the book and deserves close scrutiny.

Rist's contribution to the understanding of the American experience is threefold: he initially formulates a "theory of government bond support"; he then reviews "the possibilities of monetary policy under government bond support"; and finally, he confronts the American experience with "the theory of central banking." The support-policy experience in the United States is, of course, a unique field of study, since those few other countries that had attempted a similar course had given up much earlier (in the longer-term market, the United Kingdom in 1947 and Canada and Sweden in September 1950); as to those continental Western European countries that "insulated" a portion of government debt by requiring the commercial banks to hold secondary reserves in the form of government securities, they had done so for the purpose of restraining private credit rather than of stabilizing the terms of government borrowing, and indeed had raised interest rates as an integral part of the restrictive monetary policy. The uniqueness of the American experience is, therefore, in itself a sufficient explanation why a European student should be tempted to learn and write about it. Rist apparently also wanted to investigate, in its various phases and its outcome, a policy that he regards as having been contrary to one of the basic rules of traditional central banking, namely that credit availability can be effectively controlled only

through general or quantitative action, which in turn implies a flexible interest rate pattern.

It is from this viewpoint that Rist systematically analyzes the psychological, financial, and economic consequences of the support of the government bond market by the central bank and the resulting monetization of the government debt, reviews the controversy between the monetary and the fiscal authorities that marked the United States scene from 1945 to early 1951, and endeavors to define the field that is left under these circumstances for monetary policy. Rist's conclusion is that, within the framework of such a support policy, the discount rate ceases to be an effective instrument, and increases in reserve requirements can be nullified by the sale of government securities by commercial banks in order to obtain reserves; nor can fiscal policy, including the accumulation of a budgetary cash surplus, be effective so long as the economy remains abnormally liquid. True, postwar inflation in the United States was limited; but that was the result principally of the adaptability and productivity of the American economy and of the willingness of the American public to retain cash, idle deposits, and government securities; in Western Europe the same policy and practices would, in Rist's opinion, end in a much greater inflation.

Against this background Rist puts forward in his final chapter the lessons to be drawn from the rediscovery of monetary policy in the United States. Rist believes, first, that effective central bank control has not been necessarily impaired by the enlargement of government debt and its wide distribution. Secondly, he strongly feels that no particular importance should be attached to any given level of interest rates, but rather that attention should be focused on credit availability. His third general observation concerns the critical rôle of the lenders in the chain through which small changes in interest rates (or the mere expectation of such changes) induced by the monetary authorities may have appreciable influence on economic activity.

What I miss here are certain qualifications and reservations that would make Rist's conclusions somewhat less categorical. More particularly, I find some difficulty in Rist's underlying assumption that the objectives of debt management differ of necessity from those of monetary management. The problem of assuring lodgment of the debt during a phase of credit restraint is a real one even though economic and monetary considerations rather than merely those of technical placement should be given the decisive weight. Nor can monetary and credit policy be worked out in the complex real world merely on the basis of elaborate models built on a few simple assumptions: to be effective, it must rest on the empirical judgments of those responsible for it, with both the money and capital markets and the general economy regarded as an integrated whole. Finally, Rist does not seem to have fully realized that the central bank is not the sole arbiter of economic and financial policy. Nevertheless, with these qualifications and reservations, Rist's book is a notable contribution to the recent writings on monetary theory and policy and deserves to be read carefully on both sides of the Atlantic.

M. A. KRIZ

New York, N.Y.

Central Banking in Undeveloped Money Markets. By S. N. SEN. (Calcutta: Bookland Ltd. 1952. Pp. viii, 246. 18*s*.)

The great interest shown in problems of economic development of underdeveloped countries makes this book a timely and useful publication. Much of what is being written about development suffers from vague generalizations since the problems involved are formidable and the geographical differences infinite. If we want to get beyond these generalizations, more detailed studies like the present one are needed. They are difficult to do. The material to be digested is large and diverse, thus making it hard for the writer to come to some tentative conclusions which are applicable beyond a very limited regional field.

Mr. Sen has written a good book which can show those who are interested in development the complexity of even limited aspects of their vast problem. It is also a concise study of modern central banking in countries which, though important, are, as a rule, not dealt with in the standard literature.

For the student of money and banking it is always fascinating to watch the time gap between the emergence of financial problems and the ability of financial institutions to deal successfully with them, or to realize that some central banks were obsolete before they started to operate. Sen's book illustrates the opposite extreme. Central banks in undeveloped countries were anachronistic because their credit instruments were designed for far more developed financial systems. In this little volume we find many case studies which can be used as warning for those who believe that they can help underdeveloped countries by directly applying to them what may be proper policies for highly developed economies. For instance, what use is there in suggesting the raising or lowering of the Bank Rate when commercial banks and other financial institutions do not discount at the central bank?

Sen gives an excellent account of the difficulties met in the application of such conservative monetary instruments as discount or open market policies in undeveloped money markets. He comes to the conclusion that the changing of reserve requirements, together with qualitative controls, should be heavily relied upon. In addition, he points out that central banks in countries with undeveloped money markets will probably be charged with the duty of helping finance development. This tends to widen their task beyond the mere control of commercial banks.

Considering the important tasks which these central banks have to fulfill and the limitations which undeveloped money markets impose on the use of traditional credit instruments, Sen comes to the conclusion that a combination of very broad powers (such as were given to those central banks which were established after World War II) with a minimum of "detailed statements of what the bank is to do under every possible sort of occasions" would be the best arrangement. However, he realizes that such a system "depends more upon the men whose business will be to run the machine than on any legal formula."

GEORGE N. HALM

Fletcher School of Law and Diplomacy

Business Finance; Investments and Security Markets; Insurance

Conference on Research in Business Finance. Held under the auspices of Universities—National Bureau Committee for Economic Research. (New York: National Bureau of Economic Research. 1952. Pp. xviii, 340. $5.00.)

Here are the texts of eight papers presented and discussed at a conference held by the Universities—National Bureau Committee in June 1950 to appraise the contemporary status of research in business finance. Planned and conducted as the conference was, the report could not and does not emerge as a monograph. With more advance communication between the participants there could have been less reiteration of the obvious and the space and talent consumed in duplication could have been used to treat areas which the survey left untouched.

Each paper is a special study in itself and the discussions that follow the papers extend well beyond the bounds of mere comment. By way of example, the paper entitled "Factors Influencing Managerial Decisions in Determining Forms of Business Financing" (a joint study by Neil H. Jacoby and J. Fred Weston) is 40 pages long and the discussions run to 11 pages; the paper in two parts by Edgar M. Hoover and Burton H. Klein, and Albert R. Koch, dealing with "Factors Influencing the Demand for Funds by Business Enterprises and the Problem of Projecting Business Capital Requirements," with discussion and comment, takes up 15 pages. This review, therefore, will be confined to general observations.

The reports are replete with references to the inadequacy, incomparability, and unsuitability of available statistical data. For example, when the flow of funds into and out of the corporate system, or an industry, or a firm is studied by the "sources and uses" approach, the bases for reconciliation of "surplus" and valuation adjustments are revealed so dimly in the income and balance sheet data that one wonders (again, as often before) why companies take the trouble to prepare these statements at all, or the Bureau of Internal Revenue to tabulate them.

It is encouraging to find the conference paying its respects to the dynamic or operational approach in contrast to the older too-long-revered static or ratio-analysis approach. One participant observed that, since most of the circulating capital of a business comes from sales, financial analysis should begin with sales methods, volume and pricing policy, and include the time factors involved. Another participant found a definite association in a growing firm between the stage and rapidity of its growth and its sources of funds. Another proposed that equity and debt capital for small and medium-sized businesses be studied by questionnaire; inquiries should be made concerning the "duties and capacities of present management, as indicated by training and experience of officers and the utilization of professional and technical assistance"—a considerable departure from balance sheet analysis! Still another urged that old firms be handled separately in global studies of asset and capital structures because new firms obtain capital from different sources and have more fixed assets.

The empiricists present complained that what men do, as put down in their records, does not reveal what men think or why they think as they do. Opinion polls were proposed: "What is the main reason you went into business for yourself?" Returns from one such revealed that two-thirds were motivated by independence, ambition, and opportunism. By contrast, there were studies which purported to find an "investment function" that was primarily related to profits. (Or are *opportunism* and *profits* interlaced?) The policy-makers, anxious as always to maintain "general economic stability and growth," reported on their search for projections, either empirical or logical, by which they might keep the investment/output ratio more stable than it has been in the past. Toward this achievement they also pleaded for better statistics and better models. As Keynesian as are the bases for projection models, one paper found that interest rates were no longer important in investment decisions and another expressed the doubt that an investment/national-product percentage established for one period could be expected to apply in the next: "Investment motives in our society are extremely complex." A list of factors determining the decisions of management with respect to kinds of financing may be found on pages 167-72, several of which could be subjects for doctors' theses or for staff research.

Old-fashioned deductive analysis did receive a respectful hearing. The paper, "Costs of Debt and Equity Funds for Business: Trends and Problems of Measurement," contained a well-reasoned treatment of basic concepts and basic issues. The author began with the hypothesis that it was to the businessman's interest to maximize his capital instead of his profits and proceeded to show that capital, when taken as the discounted value of anticipated income, had important implications for cost analysis and investment decisions provided that income be forecast in full recognition of the difference between the capitalization of net income and of net operating income—leverage being understood as a decisive factor in the choice between equity and debt financing.

Econometrics had its day in the last paper preceding the "Summary." For those interested and with faith in this methodology the paper will suggest further avenues to explore: the assumptions, the variables, and the correlations can be re-examined, rechosen, and recomputed, respectively or in any order; or the data can be further questioned and further refined, ad infinitum.

The book should prove useful to teachers with the time and to business firms and government agencies with the budgets for financial research, as well as to professors who conduct seminars in finance or help candidates to choose subjects for dissertations. The papers and discussions will suggest new areas to be worked and problems that remain to be solved.

W. Bayard Taylor

Claremont Men's College

Introduction to Business Finance. By Bion B. Howard and Miller Upton. (New York: McGraw-Hill. 1953. Pp. x, 565. $6.00.)

This is a textbook on business finance that differs considerably both in

content and angle of approach from the more widely used books on corporate finance. The authors have sought to correct what they conceive to be the defects in the traditional treatment, namely the over-emphasis on the financial problems of large corporations, the needless concern with financial institutions and instruments, and the use of space to discuss the socio-economic aspects of corporate financial policies. All of these things presumably distract the student from the central problem of administering the finances of a business and, moreover, they correlate badly with other courses taken by the student of business.

To overcome these assumed defects the authors have written a volume that is straight and undiluted *financial management*. Conceiving the most important function of a course in finance to be teaching the student how to maintain the solvency of a business and maximize its profits, the first half of the book is devoted to flow-of-funds analysis, and to budgeting and financial planning. This, in the main, represents the most radical departure from the traditional approach to an understanding of the financial problems of business. The remainder of the book is concerned with the more familiar material on various possible sources of funds. Here the authors emphasize short-term rather than long-term financing; but on the whole this section does not differ greatly from most of the existing textbooks on corporate or business finance.

Subject matter dealing with forms of business organization and types of debt and ownership securities is extremely condensed and presented in an early chapter on the sharing of risk, income and control. Similarly such topics as the valuation of a business and business failure, recapitalization and reorganization are treated as non-recurring financial problems in a brief section at the end of the book. Here the student will find almost no mention of the complicated legal procedures that are a part and parcel of the reorganization process and are usually allotted much more space. But this is in keeping with the flavor of the entire book which characteristically minimizes the legal and regulatory aspects of financial practices. The student will know that there are such things as the Securities Act of 1933, the Securities Exchange Act of 1934, and the amended Bankruptcy laws, but that is about all, for these receive little systematic treatment anywhere in the book.

This is not necessarily a weakness, for it is clear that the authors have consciously chosen to strip from the study of the financial management of a business material that they consider to be dispensable or even extraneous. Presumably most of the legal and regulatory aspects of finance can be left to the lawyers; just as the study of the nature of corporate enterprise, its position in our economic structure, and the problems of public policy it raises can be left to economists, political scientists, or philosophers. The proper study of finance is finance. And the financial manager should master the techniques of administering cash so as to maintain solvency and provide for growth. That is job enough.

This is clearly an entirely sound position to take. The test of a good textbook is the purely pragmatic one of whether it is an effective vehicle for

achieving a particular educational purpose. Howard and Upton have succeeded in providing the student of business with a thorough and reliable guide to a basic training in planning and administering the funds of a going concern, whether large or small. In general the authors build this training upon the student's knowledge of accounting—and a good grasp of accounting principles and procedures is presupposed—showing how the balance sheet and profit and loss statement can be analyzed and supplemented to reveal financial condition and the sources and uses of funds. From this they move to a long and detailed discussion of financial planning and budgeting, which, because of the unavoidable intricacies of the subject will be the hardest for the beginning student to grasp. This is the heart of the book and lends much to its distinctive character.

The remainder of the book deals with short-term sources of funds—trade credit, commercial banks, commercial paper houses factors, etc., and long-term sources of funds—bonds, stocks, loans, and owner investment. There is also a chapter on term loans and equipment financing. Here the treatment is more or less traditional with perhaps somewhat more complete coverage of short-term financing than is usually found, and with emphasis on day-to-day practical problems of all types of business. Incidentally, the reader might be inclined to ask if detailed and intricate financial planning for very small business concerns is at all realistic.

The authors have used illustrative material—usually tabular in form—with good judgment and balance. Their style of writing is direct, concise, and clear. Footnotes are reduced to a minimum. List of questions are appended to each chapter for those who wish to use them, but there are no references for further reading. Perhaps the subject matter could have been made to come alive a bit more if there were more references to actual situations and incidents, but the cost of expanding the wordage may well have been too great.

There is ample evidence of care and competency in the authorship of the book. There is no doubt that it is written by men who know the subject well and who from experience are convinced that this is the most effective way to teach it. At a few points one might quarrel about matters of emphasis, but few serious errors have crept into the book.

For those who want a strictly vocational approach to business finance, and wish above all else to train the student in the techniques of financial management, this volume has much to offer. Although the student will find the going somewhat laborious and detailed at the beginning he will be amply repaid for the extra effort—if he wants to know financial management. And many teachers who feel that existing texts are too broad in scope and give too little attention to detailed procedures will welcome this practical textbook and find that it can be used effectively in business finance courses where the student has had previous work in accounting and financial institutions.

Le Plan Schuman dans la perspective Luxembourgeoise. By LÉON METZLER. (Luxembourg: Imprimerie de la Cour Joseph Beffort. 1951. Pp. 98.)

Das Monopolverbot im Schuman-Plan. By ROBERT KRAWIELICKI. (Tübingen: J. C. B. Mohr [Paul Siebeck]. 1952. Pp. ix, 122.)

The literature on the Schuman Plan is already voluminous, and miscellaneous in quality and usefulness. A German bibliography published early in 1953 lists over 1300 items, the majority, of course, magazine articles and pamphlets.[1] A few of these are of considerable value for their analysis, their facts, or their expressions of points of view; most are descriptive, and therefore inevitably repetitious, or they present well-known arguments uncritically. Parliamentary debates, including committee reports, are by far the most interesting and enlightening parts of the official literature, though government pronouncements on the aims and rationale of the heavy industry pool are not to be neglected. A new flow of important publications is now coming from the European Coal and Steel Community, which began functioning in the fall of 1952. So far this material includes a *Journal Officiel,* published from time to time, that records the acts of the High Authority and other agencies, and, in supplements, prints the debates of the Common Assembly; two reports by the High Authority; a mimeographed series of press releases under the general heading of *Bulletin d'Information;* and several mimeographed and printed statements and reports.

There are also a number of books devoted to the Schuman Plan, most of them listed above. The detailed, careful, objective analysis prepared by a study group of the Institut des Relations Internationales of Brussels may well become a standard work. This book is primarily concerned with organizational and, to some extent, juridical matters, especially the distribution of powers and functions among the organs of the Community and between the Community and the participating governments and enterprises. This may sound arid and uninteresting to those who want to know about the economic and

[1] Institut für Europäische Politik und Wirtschaft, *Bibliographie zum Schumanplan, 1950-1952* (Frankfurt am Main, 1953), 151 pp., mimeographed.

political problems of the Coal and Steel Community but the analysis has a significant bearing on these problems and is of basic importance for anyone who wishes to make a close study of this new venture in European cooperation. Take, for example, pages 35 to 53, where over one-hundred powers of the High Authority are grouped in fourteen categories, according to that body's freedom of action, its need to consult other bodies or get their agreement, etc. This sounds dry as dust, and so it is if you try to read it through, but it is an essential step in studying one of the key questions about the Schuman Plan: How much truly supranational authority is there, and how much is left to national governments, acting separately or through the Council of Ministers?

Much of the Belgian group's book brings together and interprets the provisions of the long and complicated treaty, a service that is particularly valuable in the matters of prices, cartels and concentrations, and the relations of Schuman Plan countries with third countries. Several more general chapters discuss the organizational nature of the Coal and Steel Community and compare it to other kinds of international arrangements and federations. There is a systematic comparison of the aims, organization and methods of the Schuman Plan with those of the prewar international steel cartels; and several contributors refer to the compromise of economic philosophies apparent in the treaty. No striking new conclusions about the Schuman Plan emerge from this book, but the study group has produced a painstaking handbook and guide that throws light on the treaty and provides tools of analysis for which those who come after should be grateful. A job worth doing has been well done and will now not have to be done again.

Dr. Hahn begins with an analysis that incorporates many of the criticisms of the Schuman Plan that have been made in Germany. Allied controls over production, the lack of recent investment in heavy industry, and decartelization give Germany a poor starting position compared with France where steel production has been expanded and modernized, according to this view. All the other countries in the Community have a common interest in getting easier access to German coal, but nothing is done to help Germany get iron ore: French African supplies are not covered by the treaty and the new arrangements may hamper Germany's freedom of action in exporting coal in exchange for Swedish iron ore. This case rests in part on the assumption that the members of the High Authority will continue to reflect the interests of the countries from which they come, instead of acting as supranational officials, pursuing the best interests of the whole Community. Hahn prefers the more flexible arrangements of the prewar cartels, in which a member's influence was closely related to his economic strength; he also argues that a more workable compromise of national interests would be assured by requiring unanimity on major issues.

The main contribution of this book lies in a long chapter examining the possible effects of the Schuman Plan on costs in the French and German steel industries. Hahn expects no radical changes. Lorraine iron ore is of secondary importance to the Ruhr, and the treaty will not help reduce the cost of

Swedish, Spanish or African ore. German coke is unlikely to be much cheaper in France than it was before, for a variety of reasons; moreover, in Hahn's opinion, new processes will soon permit Lorraine to supply its own coke. Wage rates plus taxes and social charges vary less than is ordinarily supposed, according to Hahn's calculations, and in any case are much less important than raw materials in determining steel costs. He adduces many other considerations to support this line of argument. At times one suspects Hahn of the *de minimis* fallacy: having calculated that not much reduction in costs will result from this or that effect of the treaty, he dismisses the subject without allowing for the possible cumulation of small items. Nevertheless, the argument is fairly persuasive, at least so far as the first few years of the Schuman Plan are concerned.

It is not always clear how far into the future Hahn means to project his conclusions. Some of the arguments about the level of costs would seem to apply for a long time to come, but might be offset by changes resulting from the common market and the High Authority's guidance of new investment. Hahn argues, however, that a common market confined to heavy industry is unlikely to help much in raising the general level of European demand. Only if a large market develops for durable consumers goods and other products using steel can the new French continuous strip mills bring costs down to American levels, in Hahn's view. (Recent studies by the Economic Commission for Europe, on the other hand, stress the effects of lower steel prices in stimulating demand). Nor does Hahn think that the Schuman Plan can do much to stabilize the European economy, so long as it is confined to coal and steel.

These considerations reinforce a view Hahn shares with many who have examined the Schuman Plan: that it cannot work effectively so long as monetary and fiscal policies are wholly in the hands of national governments. In these circumstances, Hahn believes, the price system cannot work effectively in the common market and investments will continue to be made primarily on political grounds. Believing that for political reasons the Schuman Plan must be made to work, he argues that the High Authority must begin by performing cartel-like functions. Then, the only way to avoid some kind of super-*dirigisme*, will be to create a unified European market in all fields. Not all of Hahn's arguments are convincing, but his thoughtful and knowledgeable book needs to be taken seriously. It is valuable, too, for the large body of rather detailed information it contains on the French and German steel industries.

As Haussmann's title indicates, his main aim is to show that the Schuman Plan is not as simple and clear-cut as many statements about it imply. The book is successful in achieving this admirable purpose even though its chapters are of somewhat uneven quality, not all of them closely related to the main line of reasoning. Some are useful reports on reactions to the Schuman Plan in major countries, illustrated by copious quotations. There is a heavy attack on the German neoliberal school of economic thought but it is not always clear whether Haussmann is objecting to what he considers a false interpretation of the treaty by the school or an undue influence of this line of thought on the drafting of the treaty. There is an interesting analysis of

the probable connection between the Monnet Plan for French investment and the expected enlargement of the European market through the Schuman Plan. Lengthy appendixes include information and statements on a variety of subjects, some of them peripheral to the main theme, and also the German text of the treaty.

Kövér's book is a good deal less critical than those mentioned so far. Much of it is a rather general discussion of what may be called the "official doctrine" of the Schuman Plan. The stress is on the hopes invested in the plan and on the great changes that may come about. But there are warnings of pitfalls and particularly of the difficulties that may result if supranational arrangements do not emerge in other fields as well. The most interesting part of the book is the commentary on the labor provisions of the treaty and the speculation about some of the political and economic problems that may arise. Kövér points out that the nature of industrial organizations may be much influenced by the treaty's stipulation that the High Authority can call for information from producers' associations only if they "give a satisfactory place in their organization to the expression of the workers' and consumers' interests" (Article 48). It would have been interesting if he had pursued this thought somewhat further and discussed its possible syndicalist or corporativist implications. In addition to the French text of the treaty, the appendix contains a useful tabulation of some of the powers of the High Authority and of the Council of Ministers.

Writing before the treaty was ratified, Metzler was fearful that in a common market Luxembourg would suffer great disadvantages because of its high wages and social charges. The longest chapter in the book, staccato, aphoristic, and very general in statement, is an exhortation for a changed attitude in Luxembourg's domestic affairs so as to ensure its ability to compete. So far as the Schuman Plan proper is concerned, the book is useful primarily for some details it gives about the special position of Luxembourg where 85 per cent of the economic activity is in coal and steel, and for a rather full statement of the view that cartels are useful instruments of industrial organization and government. At the beginning of the book the author appears to endorse the Schuman Plan, but at the end he calls for a re-examination of it.

Krawielicki participated in the negotiation of the Schuman Plan treaty as an official of the German Ministry of Justice and is now in the legal division of the High Authority. His book is an exegesis of the passages in the treaty referring to restrictive practices and the concentration of economic power. He calls attention to problems of interpretation, explains the philosophy of certain provisions, and compares the treaty principles and language with past and proposed German cartel law, with some references to French administrative law and American antitrust concepts. While Krawielicki does not elaborate any general philosophy about cartels and competition, it is plain from his analysis that he regards a free competitive market as of the essence of the Schuman Plan and interprets the treaty as providing quite clear law on the subject. Haussman devotes an appendix to a highly critical review of the book, attacking it as oversimplified law and economics. There is substance to some of these objections but Krawielicki's guidebook is something one

ought to consult before reaching conclusions about the meaning of the treaty's provisions on restrictive practices and the concentration of economic power.

Taken together these books, and particularly the first four of them, contribute substantially to an understanding of the nature of the Schuman Plan treaty, the problems facing the European Coal and Steel Community, and some of the main attitudes toward the new venture that exist in Europe. They are far from exhausting the subject and for any thoroughgoing study have to be supplemented by periodicals and documents. None of them is the comprehensive and well-rounded book one would like to have available for those who cannot devote a lot of time to the subject. So far as assessing the Schuman Plan is concerned, only one common conclusion emerges from these books, and that is the obvious and commonsense conclusion of almost everyone who has looked seriously into the matter. It is the conclusion that begins, "It all depends. . . ." So annoying to enthusiasts or to those who want to *know* what is going to happen, it is plainly the only general statement for which there is adequate intellectual warrant. So cautious a view does not encourage eloquence, but the Belgian study group's report puts the matter as well as anyone (p. 323):

> As to the future of the institution, one can say that it will depend on the policy followed by the High Authority and on the attitude adopted by national interests. The instrument exists. Without being perfect, it incorporates a balance of tendencies that makes success possible. Everything will depend on the intelligence with which the instrument is used and on the way in which the first difficulties are resolved.

The Sterling Area. By A. R. Conan. (London: Macmillan. 1952. Pp. ix, 192. 16 *s.*)

Britain, the Sterling Area, and Europe. By F. V. Meyer. (Cambridge: Bowes & Bowes. 1952. Pp. viii, 148. 21 *s.*)

The Sterling Area—An American Analysis. By The Special Mission to the United Kingdom, under the direction of John M. Cassels. (London: Economic Cooperation Administration. Washington: Supt. Docs. 1951. Pp. 668. $3.00.)

During the critical years of the postwar period, when the British pound underwent first a convertibility crisis, then a devaluation crisis, and finally a rearmament crisis, there has been a dearth of both reference and analytical material on the relationship of Britain with those overseas regions inseparably linked to British difficulties through operation of the Sterling Area system. These three books are designed to fill the gaps in our knowledge of the Area's operation and difficulties. The authors are notably successful in certain respects, only partially so or not at all in others.

The need for collected reference material on Sterling Area member countries

is met in a comprehensive fashion in the Economic Cooperation Administration study directed by John Cassels, which provides a summary of the postwar economic developments of the Sterling Area as a unit (with special reference to its dollar position), of the individual economies of independent members and colonies, and of the main commodities in Sterling Area trade—this last of special importance in view of the awakening American interest in the world resource picture. With elaborate charts, extensive tables, and a text which is clear and concise but does not go beyond a factual summary of the relevant economic information, this book will serve as a useful reference work for a number of years to come, not only for those interested in the Sterling Area or the British Commonwealth but also for all students of international economics.

The problems of the Sterling Area are both external and internal; important changes have taken place since the 1930's in (1) the Area's balance of payments position with the outside world, and (2) the internal mechanism and center of gravity among members of the monetary group. In assessing the nature of the Area's difficulties, F. V. Meyer and A. R. Conan attempt to determine whether it is the United Kingdom or the R. S. A. (Rest of the Sterling Area) which has been responsible for the balance of payments difficulties with the whole nonsterling world. Conan (p. 65) adds the total current balance of each member region and terms the sum the current balance for the Sterling Area, arguing that in 1938 the United Kingdom contributed 70 per cent of the Sterling Area deficit, whereas in 1947 the ratio was 50/50 and in 1948/49 the United Kingdom was in equilibrium while the over-all deficit was on overseas account. This is misleading, for it includes intra-Area transactions. The United Kingdom's position is made to look favorable only because it has had a surplus with R. S. A. throughout the postwar period, a surplus generated by use of sterling balances and protected by discriminatory exchange controls. Meyer (p. 71) takes account of intra-Area trade by adjusting for the change in intra-Area sterling balances (unrequited exports and imports), a technique which proves very confusing for the reader and would not seem to be any more correct than merely eliminating intra-Area current surpluses and deficits; but at any rate, Meyer gives a truer account of the relative position with the nonsterling world of the United Kingdom vis-à-vis R. S. A. than does Conan.

When, however, it comes to the responsibility for the dollar drain in particular, Meyer is inconsistent with his earlier reasoning on the total deficit, viz., that intra-Area balances must be considered in computations. As a result, he grossly exaggerates the United Kingdom's contributions to the Pool. The assertion that ". . . it is justifiable to regard any United Kingdom surplus on the balance of payments on current account as a contribution to the Pool, however indirect, if this surplus is due to a surplus with the R. S. A." (p. 78) appears untenable to this reviewer, and will no doubt seem a little unfair to member governments who have reluctantly, for one reason or another, given up dollar earnings for British goods in the face of agreements on discriminatory exchange control regulations.

Conan, on the other hand, determines his estimates of responsibility for the

dollar difficulties solely on the basis of commodity trade. Presumably he uses this technique in order to break down the position for individual overseas members, which Meyer does not attempt to do at all. Actually, fairly good approximations of total dollar drawings and contributions of individual members can be formed from bits and pieces of published material.

In spite of these statistical deficiencies, Conan draws some interesting conclusions from his evidence. He determines that the Sterling Areas's position with the nonsterling world has changed little *in real terms*, but rather that it has been the price changes which have been crucial. Before the war, the Area as a whole had a commodity deficit, both with the rest of the world and with the Dollar Area in particular. Therefore, an equal proportionate rise in export and import prices (the volume of trade unchanged) would enlarge the deficit. Such a commodity price rise does not, however, increase investment income and other invisible receipts nor the value of new gold production, both of which were used to meet the commodity trade deficit before the war. But not only did all commodity prices rise with the exception of gold up to September 1949; there was in addition an adverse shift in the terms of trade for the Sterling Area as a whole. These conditions meant that the Sterling Area in 1948 could export 171 per cent more to the Dollar Area than in 1938, import only 10 per cent more, and yet have serious dollar difficulties.

Any policies directed toward solving the Sterling Area's external balance of payments difficulties *must* take into account the internal operation and cohesiveness of the system. Interpretive analysis of the internal problems of the Sterling Area has in the past, however, been woefully weak, consisting for the most part of 30 or 40 articles written by economists or bankers. Almost all of these writers have been chained to one line of thought: the postwar Sterling Area system is a "natural" outgrowth of the *de facto* sterling exchange standard which existed before World War I and the voluntary association of the 1930's called the "Sterling Bloc"; and there has been little essential change in the operation of the network or in the traditional bonds which hold it together, viz., the large volume of complementary trade, the use of London as a financial center and source of capital, and the common political heritage of member regions. Meyer tends to perpetuate this interpretation through taxonomic analysis of the cohesiveness of the system. Conan's work, on the other hand, while ostensibly limited to a factual summary of changes which have taken place within the Sterling Area, shows in an implicit fashion at least some of the war and postwar developments which have lessened the pull of the center on overseas members, thus making the system less cohesive than is usually assumed.

Meyer is convinced that any solution of British difficulties is dependent upon an extension of activity overseas and the least painful way to accomplish this is to develop new markets. Most of Meyer's book is devoted to showing that extension into the Sterling Area and Western Europe is not only possible but profitable, both for Great Britain and for the other members of each group as well. British efforts should thus be directed toward a tightening and strengthening of already strong ties with each monetary region (in the case

of Western Europe possibly through a customs union) rather than toward nondiscriminatory multilateral trade.

The benefits which might be derived from a customs union with competing economies in Western Europe appear to Meyer to stem largely from the great external strength (bargaining or monopoly power) afforded the participants in their dealings with the rest of the world. An appendix using reciprocal-demand analysis indicates the conditions under which such bargaining power through the customs union device may be most effective. While many may question Meyer's objectives in proposing such a union, his reasoning is probably sound. This is not true, however, when he argues the case of mutual profitability of existing Sterling Area arrangements with an eye toward extending economic activity in this direction.

According to Meyer, there are two main advantages to the postwar Sterling Area system which accrue to the United Kingdom and to overseas members alike: (1) stability in exchange rates afforded by operation of the sterling exchange standard, *i.e.*, the holding of reserves in London by overseas members; and (2) access to the Dollar Pool, which reduces the need for import restriction and the accumulation of larger individual reserves on the part of member countries. Because of the complementary trade between the United Kingdom and overseas regions, the effect on exchange rates of cyclical swings in the relationship between prices of primary products and of manufactured goods will be minimized by increased loans to Britain in the form of sterling balances when the prices of primary products increase relative to prices of manufactured goods, and by the drawing of sterling balances when the terms of trade shift in the opposite direction. Without such a union, a decline in primary product prices which was more severe than a decline in prices of manufactured goods would mean appreciation of sterling and a consequent intensification of the adverse shift in terms for primary producers. Similarly, a primary product boom would, without monetary union, mean an even greater favorable shift in terms, because sterling would be devalued. Alternative gains and losses under different conditions are carefully worked out by Meyer, but the general conclusion is that overseas members of the Sterling Area gain as much as, if not more than, the United Kingdom by stabilization of the external value of sterling through operation of the sterling exchange standard.

The advantages of the Sterling Area financial mechanism have traditionally been an important cohesive element. But stability in exchange rates is not costless, and Meyer throws in the "costs" as merely an afterthought. First, there is the fact that the burden of building up reserves (in the sense of giving up goods) falls on the overseas members; they are lending to Great Britain and withdrawing their own loans, not vice versa. Secondly, while shifts in real income *consequent upon changes in the terms of trade* may be minimized, as Meyer indicates, by stability in exchange rates under the sterling exchange mechanism, stabilization of members' internal economies is probably thereby made more difficult. For example, in a period when primary product prices were falling by more than prices of manufactured goods, the deficit would probably be larger, and the deflationary income, price, and money supply

effects more severe in the overseas country if the external value of sterling remained unchanged than if sterling were appreciated.

Conan points out that the continued strengthening of desires for monetary independence on the part of overseas Sterling Area members (begun with the establishment of central banks) runs counter to the present nature of the Sterling Area financial network. Of course, membership in the Sterling Area does not prevent altering the value of a currency relative to sterling. The very fact that members have done so (New Zealand in 1948, Pakistan in 1949, and Iceland in 1950) indicates that there are limits to the advantages of stable exchange rates, although it is true that members have been reluctant to change parities, choosing often to adopt controls—even on Sterling Area transactions—rather than vary the exchange rate. Intra-Area restrictions in the postwar period have been used much more extensively than Meyer indicates (p. 31), especially with respect to Far Eastern member countries.

Furthermore, the financial advantages of the Sterling Area system, such as they are, form only one of many factors which must be considered by overseas members, and they are advantages which could be enjoyed without full membership, as Egypt has shown since 1947. Meyer seems to think only in terms of two alternatives: full membership versus freely fluctuating, or in some cases variable, exchange rates. But a member could accept transferable account status and handle its own dollar reserves if it wished to, or it might achieve exchange rate stability by holding reserves in various countries including the United States, especially if, as is true in a number of cases, the United States is beginning to rival Britain as a trading partner. The ties which might enable Great Britain to extend its markets into the overseas Sterling Area are primarily members' interest in Britain as a source of capital, in Britain as a holder of balances which may be blocked, and in the Dollar Pool, and only secondarily the tie to the financial mechanism.

Meyer recognizes the Dollar Pool consideration, but he makes no attempt to analyze the drawings and contributions of individual members. The Dollar Pool *is* a tie for most independent members; in fact, most drew more from the Pool than they contributed between 1946 and 1952, the exceptions being South Africa (which does not directly contribute to the Pool but sells gold to Britain by agreement) and Ceylon. But Britain, without aid, has easily been the largest single user; its unaided dollar deficit plus that of some of the colonies have together exceeded by a substantial amount the net contributions of the few dollar-earning colonies, notably Malaya and West Africa. Thus, if American aid were sharply reduced or eliminated, the Pool might prove to have little attraction for independent members of the Area. The Ceylonese government has been desirous of, and partially successful in, maintaining its own dollar reserves. Australia and India both considered leaving the Dollar Pool arrangement when they were earning rather than drawing dollars in 1950.

Both the financial mechanism and the Dollar Pool are thus tenuous bonds for the overseas Sterling Area, clearly not the one-sided considerations that Meyer indicates. But the hold over members through control or potential control of capital outflow from Britain and through the possibility of blocking

and releasing the sterling balances has also been important. Meyer takes no note of either of these factors in considering possible British policy. He states that "The United Kingdom has never imposed any restrictions on the inward or outward flow of private sterling funds from and to the R. S. A. . . ." (p. 31). This is not true. Through control over capital issues, Britain has been able to govern borrowing from abroad on the London market, and this device was used in the gold agreement with South Africa in 1949. The potential restriction of capital outflow has always been present, and clearly Britain would be reluctant to send scarce capital funds to a country which chose to give up full membership for a transferable account status. But how important today is this traditional attraction for overseas countries? Conan shows in Chapter 4 that the prewar debtor-creditor relationships within the Sterling Area have changed markedly. Overseas countries have greater flexibility because interest and dividend payments to the United Kingdom have shrunk so considerably, and the existence of sterling balances has meant that dependence on Britain for new capital funds has diminished. Even when the balances are down to working minimums, it seems doubtful that the British can supply much of the capital which will be needed, and if this is so, member countries are bound to look elsewhere.

Elimination of "excess" balances (envisaged by 1956 for India, Pakistan, and Ceylon under the Colombo Plan) will remove the last ace Britain has had up her sleeve as a means of maintaining control over the Sterling Area. While Britain has been more than generous in releasing sterling balances, overseas members, especially India, have clearly recognized that pressure could be used if necessary along these lines, as is clear from accounts in the *Eastern Economist* and elsewhere.

The sparse reports on recent negotiations between Britain and the United States indicate that the British government has been reading between the lines of Conan's book rather than accepting Meyer's conclusions. Undoubtedly, the British have felt pressures from overseas members of the Sterling Area on the need for convertibility and some closer link to the dollar rather than a further turning inward such as Meyer proposes.

PHILIP W. BELL

Haverford College

Foreign Aid by the United States Government 1940-1951. Supplement to the *Survey of Current Business*. Prepared by the Clearing Office for Foreign Transactions, Office of Business Economics, U. S. Department of Commerce. (Washington: Supt. Docs. 1952. Pp. 118. $1.00.)

This volume brings together in comprehensive and convenient form the record of total United States government foreign economic aid over the eleven-year period from July 1940 to July 1951. More recent data on United States foreign aid since July 1951 are published in periodic articles of the *Survey of Current Business*, the last of which appeared in the March 1953 issue.

It is surely no exaggeration to say with the editors of this book that "the

foreign assistance rendered by the United States and described in this volume represents a series of programs unique in economic and political history." The total aid furnished to foreign countries (exclusive of our contributions to the Monetary Fund and the International Bank) over the eleven-year period aggregated 82 billion dollars, of which 49 billion dollars was provided during the war period. Reciprocal foreign aid to the United States offset a part of this total, so that the net aid extended to foreign countries by the United States government totaled 72 billion dollars.

If we add to these over-all figures the amounts of United States government aid extended from July 1951 to the close of 1952, the gross aid figure rises to 90.5 billion dollars and the net aid total is nearly 79 billion dollars. The net foreign aid extended by the United States government for all purposes since the close of the second World War through 1952 totals 38 billion dollars, only three billion dollars less than the net aid provided by the United States government to other countries during the five-year war period. It seems altogether likely that the 1953 figures will cause the totals of postwar foreign aid of the United States government to rise above the dollar total of our wartime lend-lease effort, once—not so very long ago—regarded as the all-time high of imaginative national effort in surmounting the limitations of conventional international finance.

The present volume is not intended to be an appraisal of the results of the tremendous and persistent efforts of the United States government to shape the course of international development over the last dozen years. Nor is it meant as a theoretical analysis of our international economic relations. Its purpose is, rather, to present and classify the voluminous and complicated facts in an orderly and systematic manner as a basis for theoretical speculation or policy formation. As such, it is indispensable for any thorough study of the rôle of the United States in world affairs.

The illustrated main text of the book emphasizes three aspects of our foreign aid. First, it explains the basic objectives of the different aid programs and the circumstances out of which they arose. Secondly, it describes the geographic distribution of aid by countries and main geographic areas; and finally, it presents an historical account annually and by periods of the magnitude of United States aid and the shifting emphasis from grants to credits and back to grants. This is followed by an appendix of statistical tables with full explanation of the concepts and definitions employed in the compilation of the data, and a legislative appendix summarizing the major legislation relating to foreign aid from 1940 to 1951. Most readers would probably agree that the facts presented here flow in such orderly and abundant profusion as to satisfy even the most vigorous intellectual appetites for some time to come.

Among the many data assembled in this volume this reviewer's eye was caught by Table H which shows total credits of nearly 12 billion dollars granted to and utilized by foreign governments in this period, of which between 10 and 11 billion dollars are still outstanding. These foreign debts had grown very rapidly in the years 1946-1948 prior to the beginning of the European recovery program, and continued to expand thereafter, though at a much slower rate. Table K projects the contractual debt service on this

foreign indebtedness through 1961, showing that amounts between 400 and 500 million dollars annually are scheduled to be paid to the United States by foreign governments in interest and repayment of principal on accumulated intergovernmental debts. These two tables may help to remind us—if any reminder is needed—that our balance of payments problems and the policies pertaining thereto are likely to be as important an item on the agendas of future international conferences as they have been in the recent past.

MAX GIDEONSE

Rutgers University

Banking and Foreign Trade. A series of lectures delivered at the Fifth International Banking Summer School, Oxford University, 1952. (London: Europa Publications Ltd. 1952. Pp. 256. 15 *s*.)

The postwar period has not exactly displayed a lack of writing on international economic problems. Faced with an avalanche of books and articles, the general economist will find the present volume a useful survey of the most important recent trends and policies in international economics. It can be assumed that this is what the book was designed for, and on this score it comes out well. A group of bankers, economists, and civil servants deal, each from his own viewpoint and philosophy, with some particular aspect of the total picture. The selection of speakers is on the whole good, although the caliber of the papers is uneven. This is perhaps unavoidable in a joint enterprise of this nature.

For the specialist in the field the volume has much less to offer. It does not reveal any new insights, and the papers which deal with policy questions express opinions which are on the whole familiar in the literature. For example, the reader will look in vain for new approaches to the pressing problems of discrimination and convertibility. The one exception is, in this reviewer's opinion, a highly interesting paper by R. F. Kahn in which he discusses the postwar monetary and commercial arrangements. His position is, briefly, that the nondiscriminatory elements in the Articles of Agreement of the International Monetary Fund are much less objectionable than the corresponding rules in the ITO Charter and GATT. But let me use his own concluding words: "When I offer, in perhaps patronizing fashion, a benevolent word in favour of convertibility, as laid down in the Articles of Agreement of the International Monetary Fund, I am only following Lord Keynes, who expressed himself in favour of the use of powers of negotiation and of bilateral arrangements about trade, but wanted to be sure that in the upshot anything which resulted from trade negotiations was made possible by suitable exchange arrangements. . . . What I am saying is that if we had enough trade discrimination, harmoniously and constructively administered, we might be able to introduce convertibility on current account." Whatever the merits of his case may be, it seems to represent an important kernel in current British thinking, and as such it calls for serious consideration.

Economic Replacement Policy. By ARMEN A. ALCHIAN. (Santa Monica, Calif: The RAND Corporation. 1952. pp. ix, 129.)

This study deals with the important problem of when to replace units of durable equipment by similar or improved units. Beginning with a formula which is correct in theory and when forecasts are accurate, it is the author's purpose to show that by computations which can be reduced to simplified form a correct replacement decision can be made. As the stream of income declines over time and possible alternate equipment becomes available, the replacement should take place when this stream of services can be secured at a lower cost or, in other words, when a new service is worth more than the increased cost. In his introductory chapter, Alchian defines these costs of providing this stream of service as related to the current value of the existing equipment, the net cost of switching to the new equipment, the cost of replacement at projected intervals, operating costs, and the operating costs of the series of future replacements. Replacement decisions will rest on the comparison of the present value of these costs with the discounted value of the service stream. Advantages and disadvantages must be compared in time and it becomes necessary to recognize the element of interest by a discounting process. This study takes pains to point out that the correctness of decisions depends on the accuracy of the data necessary for the forecasts.

The reader with mathematical facility will find in Chapter 3 a concise statement of the basic elements outlined in the introductory chapter. In short, the formulation begins with a notation of the variables and then sets out, by mathematical expressions in terms of present values, the various elements of costs (E), such as the cost of switching from existing machines to a new one or the costs of operating the present equipment. The value of the revenue or services of a machine (R) is also given expression in terms of present values. The next step, after all elements are set forth, is to give exponential forms to E and R. Thirdly, R and E are integrated in order to provide a simple and easy method of computation. For example, this process gives us six terms for cost (E_1, E_2, E_3, etc.) each of which is a product with a dollar coefficient. To afford a rapid computation these factor values are set out in the appendix. For example, to find factor IV it is necessary simply to turn to the table and read the number for the two variables and then apply the money value. Finally, there is a summation of these costs.

This study will be appraised by its readers on two entirely different levels. The first sort of appraisal will be made by a small group of theorists who are interested in replacement theory and are able to apply the techniques of advanced mathematics. The problem of replacement is really one of interest and investment. In order to see the relationship of this study, the average reader who is unfamiliar with the literature in this field might well begin with a review of parts of Irving Fisher's *The Theory of Interest*. J. S. Taylor appears to have been the first writer to set up an algebraic formula to show the determination of the life of a machine when unit cost and interest are at

a minimum.[1] Hotelling, Roos, Preinreich, and others have made modifications and new formulae to expand their treatment beyond cost comparisons. In an attempt to present an approach which would appeal to engineers and business men, George Terborgh brought out in 1949 his study under the title of *Dynamic Equipment Policy.*[2] One formula may be an improvement over its predecessor and concepts may be greatly expanded; at the same time, these mathematical theorists would agree that the replacement problem cannot be reduced to any final form simply solvable statistically. All predictions must be made on the basis of what will happen to the average machine. We cannot predict the kind of machines men may make. With psychological factors involved, it would be an extremely complicated procedure to introduce the factor of uncertainty into the formulation. Again, if wear and tear is the important factor of depreciation and production varies greatly in time periods, then a forecast of straight line depreciation is theoretically incorrect. It is extremely important to keep in mind that in these formulae we assume a constant price level and also no change in interest rates. If we believe that prices will decline, then replacement should take place somewhat later than indicated by the formula; if we believe interest rates will rise and capital will become more expensive, then there will be another factor favoring replacement. Decisions must also shift with the interest rate selected. Should we select a "pure" interest rate, a rate high enough to attract capital in the industry, or some other rate? In the absence of a reliable system of forecasting, no formula can give effect to the principle that cost and revenue factors should be measured in units of equal purchasing power instead of the customary dollar unit.[3] As we go into long periods of time, the compound interest process takes on great powers of growth and we see our data in the far away and dim shadows of discounted futurity. (At 6% the present value of one dollar in thirty years is thirty-one cents; in fifty years, it is only five cents.) Preinreich some years ago, apparently with a certain sense of futility, concluded one of his articles on this problem as follows: "I am not greatly impressed by the practical merits of the theory of economic life, although it is no doubt a fascinating subject, worthy of study for the sake of its legitimate place in economics."[4] Whatever other merits these theorists may find, Alchian appears to have made a contribution in his use of exponentials and his adaptation of the computation to electronic machines.

An appraisal on a second level will be made by business men, engineers, and accountants. As we attempt to apply the principles set forth to a particular problem or plant, certain limitations will become apparent. A possible saving through the purchase of new equipment is only one of the reasons for replacement as there might be a hazard connected with the machine causing

[4] *Op. cit.,* p. 39.

accidents and interruption of service. Does accurate data for forecasts, which the study emphasizes as fundamental, exist in every case? The central problem appears to be an inability to estimate revenue for particular items of equipment. What is the value of the services of a desk in an insurance office or the boiler of a public utility? Sales result from the combined services of many items of equipment and may also involve items of rent and monopoly elements. The fact that accountants do not as a rule accept the principle of charging interest on equity capital is not important for this analysis. It does, however, seem that such computations will have significance only when they are made for relatively short periods of time. Although this study should not be turned over to a clerk with a calculating machine, there is a real achievement in the reduction of a complicated problem to a simple and quick method of computation. Its value lies in the possibility that it presents for improvements over present rule-of-thumb methods. I do not believe that the business men who will test this study will become so involved in mathematical techniques that they will fail to rely upon independent judgment as well as the proposals in it as a guide to equipment replacement.

Industrial Organization; Public Regulation of Business

Monopoly and Social Control. By HENRY A. WELLS. (Washington: Public Affairs Press. 1952. Pp. ix, 158. $3.25.)

Mr. Wells here essays a formidable task. He tries to analyze the American monopoly problem in terms of man's persistent attempts to modify and control his social and economic environment. Given Wells' brevity of treatment and choice of emphasis it is not surprising that his effort is largely unsuccessful.

Wells' analysis and prescriptions rest on several presuppositions. They may be summarized as follows: First, industrial concentration is continuously and rapidly increasing in the United States. In this he roughly follows the John Blair-Federal Trade Commission position recently questioned by Adelman, Lintner and Butters.[1] Second, concentration of industry is equivalent to or even underestimates the extent of monopoly about which he is concerned. Therefore, the rate at which monopoly is increasing is alarming. Third, monopoly is the chief cause of our economic maladjustments. To it may be attributed, among other things, both depression and inflation. The excision of monopoly would, then, remedy our chief economic defects. Fourth, the expansive phase of capitalism has ended, and the growth factors that served to divert public attention from the development of monopoly are now ex-

[1] M. A. Adelman, "The Measurement of Industrial Concentration," *Rev. Econ. Stat.*, Nov. 1951, XXXIII, 269-96; Corwin Edwards, George Stocking, Edwin George, and A. A. Berle, Jr., "Four Comments on 'The Measurement of Industrial Concentration'," *ibid.*, May 1952, XXXIV, 156-74; M. A. Adelman, "Rejoinder," *ibid.*, 174-78; John M. Blair, "'The Measurement of Industrial Concentration': A Reply," *ibid.*, Nov. 1952, 343-55; M. A. Adelman, "Rejoinder," *ibid.*, 356-64; John Lintner and J. Keith Butters, "Further Rejoinder," *ibid.*, 364-67.

hausted. Fifth, the continuation of the trend to monopoly would undermine the American faith in free enterprise and political democracy.

Although these are not unfamiliar or perhaps even unpopular propositions, the validity of the first four of them, at least, is highly questionable. Upon these assumptions, whose validity he does not prove, Wells builds his analysis.

As Wells sees it, the central monopoly problem is whether a democracy can, without destroying itself, reverse the tendency of private monopoly to dominate the economic process. To solve that problem we should understand the general question of controlling man's environment. In addition, we should understand the American tradition of controlling the political and social environment, and how that tradition evolved. With these purposes in mind, Wells devotes some thirty pages to a truncated survey of political and social theory from Plato to Marx. He then turns to a brief inquiry into the nature and origins of the American pragmatic tradition. Wells concludes that certain environmental and ethnic factors have permitted in the United States a gradualistic and pragmatic approach to social and economic problems. He feels, however, that a failure to cope with the relentless growth of monopoly would cause a popular rejection of gradualism, and thus produce the contradictions and upheaval Marx predicts.

In Wells' judgment, our present plight is grave but not hopeless. He devotes the better part of 75 pages to a recital of the factors that make the task of antitrust as great as they are. First, the ownership and control of industry are already highly concentrated. And concentration (oligopoly) comes to the same thing as monopoly. Second, there is a lag between the growth of a social threat and an official and public awareness of it. Our institutional apparatus tends, therefore, to lag behind the development of those evils it is supposed to combat. Third, powerful monopolies are able to influence legislation to their own advantage. Fourth, even if appropriate antitrust legislation exists, big business can frustrate its application.

In spite of the enormity of the task facing antitrust agencies, Wells is hopeful. He takes heart in a new public awareness of the problem and in certain recent court decisions (including the Aluminum, Tobacco, Pullman, and Cement Institute cases) that make the task of winning antitrust cases somewhat less formidable.

Whatever one may feel about the need of an antitrust program, and this reviewer believes there is such a need, Wells' study is disappointing. He generally disposes of powerful counterarguments by ignoring rather than refuting them. He carefully explains why oligopolists behave like monopolists, yet disregards factors that may make them behave competitively. He turns his back on the dynamic forces that have in the past made American monopolies unstable, and denies the facts of American economic progress. He does not sufficiently consider the possibility that state-sponsored monopolies may be more dangerous than the private monopolies he abhors. He takes the questionable position that trade unions, the farm bloc, and other pressure groups are free of the unsavory motivations and evil consequences he sees in concentrated business.

From one who argues so strongly for a strengthening of antitrust we might

expect concrete suggestions. Wells, however, contributes practically nothing to the development of a workable antitrust program. The newcomer to economics will find in Wells' book much that is misleading and not much that is stimulating; students of monopoly and social control will find here little that is useful and less that is new.

Even if this book is judged as an attempt to popularize a dogma, it does not come off well. Wells' style is frequently opaque and usually discursive. The book is repetitious and disorganized.

Wendell Berge wrote the lucid but overenthusiastic introduction to the volume.

JOHN S. MCGEE

University of California, Los Angeles

Problems of Nationalized Industry. Edited by W. A. ROBSON. (New York: Oxford University Press. 1952. Pp. 390. $5.00.)

This study systematically interrogates the experience of industries and services nationalized by Britain's Labor government between 1945 and 1950. The first half consists of thirteen essays by different authors; six of these essays appeared previously in the *Political Quarterly,* April-June, 1950. In the second half, W. A. Robson, professor of public administration, University of London, synthesizes the various topics and states general conclusions.

The essays do not constitute case studies of particular nationalized industries. Instead, they have the merit of examining the major general issues relevant to most nationalized industries operated by public corporations: the basis of compensation, administrative organization, ministerial control and parliamentary responsibility, labor problems, joint consultation, the consumer's interest, public relations, price policy, financial efficiency, and scientific research. It is apparent that the political issues receive more attention than do the economic. The economic contributions are by Professors Gilbert Walker, G. D. H. Cole, W. A. Lewis, P. Sargant Florence, and Sir Arthur Salter.

Of the economic contributors, Professor Lewis on "Price Policy" and Sir Arthur Salter on the "Crux of Nationalization" provide a balanced combination—the former displaying optimism, the latter pessimism. Undismayed by all the qualifications raised in the many discussions of marginal cost pricing, Lewis proceeds directly to a promulgation of his rules (pp. 181, 190-91): "(1) It [the public corporation] should make neither a loss nor a profit after meeting all capital charges; and (2) the price it charges for different services should correspond to relative costs. . . . And if subsidies or taxes are to be levied, they should be levied only by instruction, should be shown separately in the accounts, and should be paid separately to or by the Exchequer. . . . If the different parts of the service compete with each other, relative prices must reflect (but not necessarily equal) relative marginal costs. And each part of the service should pay its own way, showing neither a profit nor a loss, except where the different parts share the same overhead costs; in this case each

must make a surplus, dependent upon its capacity to contribute to overhead costs."

Sir Arthur Salter, in contrast, is so concerned with three preliminary questions that he will have little to do with the planner's Nirvana: "How can the incentives of competition, with prospective profit or bankruptcy, which are found in private enterprise, be replaced? How can collective bargaining be adjusted to the different conditions of nationalized monopolies? And what safeguards can be found against the inherent tendency of bureaucracy to excessive centralization?"

The economic discussion is in many respects rather dated in the Lange-Lerner-Hayek days. To a considerable extent, one may feel that what would really be of interest in this field is a rewriting in terms of modern welfare economics of Pigou's earlier discussion of "Public Operation of Industries" in his *Economics of Welfare,* followed by an application of principles to the types of problems under review in this study. One especially misses more attention to some issues of marginal cost pricing as analyzed elsewhere by Crosland, Henderson, Little, and Wilson, among others. Some concern with problems of productive efficiency in state monopolies, as discussed elsewhere by Chester and Jewkes, would also have been relevant. It is at best not very satisfying, and at worst meaningless, to dismiss the latter problem merely by claiming that "statisticians are lagging behind the public need in evolving the statistical criteria necessary to determine performance" (p. 297). Even more significantly, investment policies of nationalized industries are neglected. This can not be separated from price policy and deserves attention. And finally, particular problems such as the intricacies of the road-rail and electricity-gas problems are unduly minimized. If, as is maintained, the public corporation is the "most important constitutional innovation which has been evolved in Great Britain during the past fifty years," then the concentration on administrative problems is welcome. Although the reviewer is not competent to evaluate the political contributions, nevertheless he must remark on the number of rather vacuous conclusions such as the following: "A successful balance between decentralization of management and central control of policy rests, in the last resort, on the establishment of harmonious relations between the persons concerned" (p. 90). Or, "My general conclusion on the whole subject (of the governing board of public corporations) is that it is of profound and fundamental importance that the prestige, status and dignity of these posts should be upheld and enhanced" (p. 107).

In general, the same economic problems which this work considers have already been discussed in the literature, in some instances more thoroughly. But students will find it convenient to have the problems bound between two hard covers, rather than scattered among journals and pamphlets. It is, however, regrettable that there has been a publication delay of almost two years for the treatment of materials only five years old. Problems of denationalization may now be just as topical.

G. M. Meier

Williams College

Economic Warfare. By YUAN-LI WU. (New York: Prentice-Hall. 1952. Pp. xii, 403. $4.50.)

In this book Yuan-Li Wu makes a painstaking and conscientious attempt to develop a general theory and present an historical description of economic warfare, the emphasis being heavily on the former.

The seven chapters that follow the introduction present an over-all view of the numerous measures that, in principle, a nation at war can take to strengthen its own economy and weaken that of the enemy. Two chapters cover regulation of international buying and selling. Two others consider "Aggressive and Defensive Financial Controls and Operations," one dealing with foreign asset control, and the other with something called "Foreign Exchange Budgeting Special Exchange Procedures." Another analyzes the long-term economic penetration of a developed economy with which one is not at war. Two chapters, entitled "Economic Cooperation versus the New Colonialism," based largely on U.S. policy following the war, indicate ways in which a country can enhance its international position through conditional aid rather than coercion. Two others describe World War II measures taken by the British and Americans, and make interesting reading, but German countermeasures can only be inferred. Another, on "Economic Warfare Against a Hypothetical Enemy," distills some principles and considers some likely and unlikely alignments. One chapter deals with the aftermath of economic warfare. The final chapter comments on some actual and possible U.S. policies.

Mr. Wu is at his best when outlining the multiple effects—some favorable and some unfavorable—that stem from each act of economic warfare. In framing its wartime regulations over trade and finance, a government must always compromise in its relations with neutrals, because its own bargaining power is very seldom absolute. For example, it will usually be necessary to permit some re-exports through neutrals to the enemy, especially when both neutrals and the enemy are within the effective blockade.

One fact driven home by this work is that, in economic affairs, no neutral will ever be left alone by both belligerent powers. One or other will strive, with bribery and bullying as conditions dictate, to induce neutrals to restrict their exports to hostile powers and enter more wholly into the economic orbit of its own bloc. The means employed may be different for each country depending on a multitude of factors.

It is for this reason that a discussion of economic warfare should run in terms of specifics rather than generalities. How a neutral is to be treated depends on geography, the location and effectiveness of one's blockade, the goods and services the neutral needs, and the exact nature of the commodities to be diverted for the enemy. Does the neutral have a merchant marine dependent on the maintenance facilities of one of the belligerents? Does it normally use one of the warring powers as a banker for its international transactions? What are the political sympathies of each neutral government and people?

A serious defect of *Economic Warfare* is that it attempts to develop a general theory for a subject which does not lend itself to this treatment.

Consequently the text is desiccated and laborious. Each sentence is lucid enough, and the manner of presentation is eminently logical, but the effect of piling one theoretical interaction upon another, until some large abstract monument to deduction has been constructed, is deadening. The occasional footnotes giving some historical instances are the only relief experienced in some very tedious chapters.

For this reason too it is hard to say that this book, which could have been so timely, is particularly relevant to the cold war. True, the principles of economic warfare, developed at such great length, are pertinent enough. But one learns very little, the chapters on "Economic Cooperation versus the New Colonialism" notwithstanding, about the main issues that arise, or might arise, from a determined American and British attempt to influence European and Asiatic trade with the Soviet Union and its satellites. Here was an opportunity that was not adequately developed.

Perhaps one merit of the book is that very little has been written in this field since World War II, although various activities of the last war have been described. If colleges have courses in this subject, *Economic Warfare* should be considered as a text, although the students will find this rather exciting subject unexpectedly dull reading.

STEPHEN ENKE

The RAND Corporation
Santa Monica, California

The Economics of Defense: A Primer of American Mobilization. By R. V. CLEMENCE. (Harrisburg, Pennsylvania: The Stackpole Company. 1953. Pp. 138.)

This book is intended to acquaint the reader having no previous knowledge of the subject with the basic problems faced by a mobilizing economy. The author points up the two major aspects of mobilizing for defense in a democratic nation. On the one hand, there is the problem of physical production. Manpower and other productive resources must be made available for defense purposes. On the other hand, there is the problem of preparing the citizens of a democracy for the added effort and the sacrifices which are necessary during an extended defense program. The author is primarily concerned with this latter aspect of mobilization. His main objective is to develop an analytical technique which can be used by the reader in evaluating the important policy decisions which must be made throughout a period of mobilization.

As Professor Clemens indicates, "to prepare a democracy for all-out war is a very different matter from similarly preparing a totalitarian dictatorship. . . . Mobilization in a dictatorship means telling people what to do, and making them do it" (p. 2). By contrast, in a democracy, the success of a defense program of indefinite duration depends primarily upon the voluntary cooperation of the various groups within the private sector of the economy; and a familiarity with the basic problems involved will promote more ready acceptance of the program by these groups.

The author has devoted individual chapters to a description of the peace-

time, wartime, and defense economies. The analysis in these chapters is directly related to a series of circular flow diagrams or models which present the real income and the money income relationships between the household, business, and government sectors of the economy. These models effectively illustrate the manner in which money and income flow vary between these sectors as the transition is made from a peacetime to either a defense or a wartime economy. Separate chapters consider two important phases of a mobilization program, namely, the shifting of resources to the defense area of production and the problem of inflation control. Final chapters present an analysis of indirect and direct controls and their rôle in a defense economy.

Perhaps the greatest single merit of this book is its simplicity. No attempt is made to define either the precise composition or the exact size of national output during the period of defense production. The general approach is less detailed and less technical than other works on the subject which have appeared within the past several years. The book is intended to be a primer on the economics of defense. Other more technical treatments are recommended as a sequel.

Mobilizing for defense and war has been a recurring problem in recent years. Few basic economics textbooks, however, give a fully integrated treatment of the subject. Yet the student should be familiar with, and should be able to evaluate critically, the various economic policy decisions which must be made during an extended period of defense production. A careful study of Clemens' "primer" will provide the reader with the analytical tools to better understand the economic implications of these policy decisions. The book is highly recommended for supplementary reading at the elementary level.

GERHARD N. ROSTVOLD

Pomona College

Public Utilities; Transportation; Communication

The Pacific Coast Maritime Shipping Industry, 1930-1948. Vol. 1, *An Economic Profile*. By WYTZE GORTER and GEORGE H. HILDEBRAND. (Berkeley and Los Angeles: Univ. of California Press. 1952. Pp. xiii, 118. $2.50.)

This is the first of two volumes dealing with the measurement and analysis of the economic performance of the Pacific Coast maritime shipping industry, defined in the opening chapter to include those functionaries which "move waterborne cargo and passengers[1] through ports of the Pacific Coast States in the foreign, intercoastal, coastwise, and non-contiguous trades."

The authors have specifically limited themselves in Volume I to the construction and very limited interpretation of statistical series relating to three

[1] The analysis is confined, however, to cargo movements on the ground that passenger traffic is not significant.

measures of performance: cargo tonnage, as an indicator of output; vessel arrivals, as a measure of service offered; and employment, as a measure of both employment opportunities and the degree of utilization of the rather immobile labor force associated with the industry: the choice being determined in part by the availability of data. The "economic profile" presented by these series is discussed in general terms in the second chapter and more specifically in the two following, but in each instance explanations of and inferences from the data are limited to a defense of the general thesis that the industry was declining, in absolute terms and relative to those of the Gulf and Atlantic Coast ports, throughout the period 1930-1948 except under the stimulus of war. A useful and methodical summary of the problems of data collection and their resolution and the tabular summaries referred to in the text are presented separately in appendices for clarity of exposition.

The organization and presentation of industry studies is, of course, a matter of individual preference, and the well-ordered development of this little book bears out the authors' contention that a very considerable task of data assembly and reconciliation was necessary before any meaningful analysis of causal factors could be undertaken. It is not entirely clear, however, that this fact alone warrants the separate publication of Volume I. The nontechnical reader will find it difficult to apprehend its significance in the absence of a selective description of the nature and recent evolution of the peculiar market environment in which the industry operates; and the professional in the field can hardly assess the adequacy of the measures employed or the validity of the conclusions with respect to the industry's postwar status without a more explicit statement of the coverage and technique of the causal analysis to follow.

In a similar vein, it is to be hoped that the authors' concluding statement that the central theme of the problems to be dealt with in that analysis concerns the concepts of supply and demand implies a broad reading of those terms: *i.e.*, an inclusive examination of the complex political, legal, and sociological relationships which underlie economic behavior on the Pacific Coast waterfront, and of their vital significance to the development—from among a broad range of alternatives—of short- and long-run policies of employer and union groups. The politics of regulation and of trade policy, the ideology behind the drastic revision of waterfront labor organization, and the personal rivalries of the era are difficult to fit neatly into curvilinear analysis, but they are a vital part of the framework within which economic behavior was determined in that turbulent period.

An adequate appraisal of the usefulness of this first volume must, therefore, await the second. Within the limits specified, however, it represents a scholarly and unusually well-ordered summary of one line of attack on the common problem of virtually all industry analysis: the preparation of meaningful measures of economic performance from scattered data of uneven coverage intended for a variety of purposes.

Land Economics; Agricultural Economics; Economic Geography

Resource Conservation: Economics and Policies. By S. V. Ciriacy-Wantrup. (Berkeley: University of California Press. 1952. Pp. x, 395. $6.50.)

The title of this book suggests an ambitious effort and the flyleaf confirms this. Some fourteen years of research by the author, with assistance of such groups as the Social Science Research Council and the Guggenheim Foundation, lie behind this work.

The general organization of the book is an appealing one, being logical and systematic, something not often attained in a work dealing with such an amorphous field. A review of the emergence of the problem of conservation is followed first by a classification of types of resources and then a consideration of the meaning of the term conservation. The next two sections, which occupy some forty per cent of the book, analyze the rôle of the private planning agent in the economics of conservation. Not only are the effects of decisions based upon economic motivation studied, but the institutional influences which operate upon the private planning agent to speed or retard resource use are given extensive consideration.

It is the author's view that what he calls the "optimum state of conservation" in private economics serves as a "construct" about which the forces of economic motivation and institutional influence may be grouped and analyzed. To this end the "optimum" is viewed *ex ante* to enable the economist to study the effects on conservation resulting from the motives and conscious objectives of the planning agent. The "optimum" seen *ex post* is an historical notion which it is felt will be helpful in the appraisal of "habit patterns." This latter term is used to include behavior learned through repetition and imitation rather than by conscious understanding. Having established his "constructs" Ciriacy-Wantrup gives extended treatment to the manner in which the planning agent reacts to or is acted upon by such economic and/or legal influences as: the rate of interest, time preference, income, uncertainty, prices, some aspects of property, credit, taxation, market form, and economic instability. A number of subtle relationships of varied degrees of importance are uncovered.

The final two sections are concerned with the objective, criterion, and implementation of conservation policy for society. With the society, as with the private planner, the objective is an "optimum state of conservation" but in terms of social rather than private economics. Practically, it is recognized that the theoretical "optimums," both private and social, cannot be attained in reality. In most circumstances the practical goal of conservation policy is held to be a step-by-step improvement in the existing state of conservation.

A unique but important case requires further readjustment in policy goals. This is the case of those resources which are ordinarily renewable but which have a critical zone of utilization beyond which depletion becomes irreversible within the realm of economic feasibility. Perhaps the best single illustration of such a resource is soil. The danger resulting from this irreversibility is that it may entail what are called "immoderate losses"—those which may threaten the survival of the community. Such immoderate losses to society are in terms

of narrowing the resource base of the economy and consequently reducing its adaptability and its opportunities for development. Certain social growth is stifled, some other is distorted; social collapse may result if the resource base is continually narrowed.

Irreversibility does not always result from depletion of these resources. However, it is a possibility which a society cannot afford to risk. As a safeguard against this contingency, Ciriacy-Wantrup develops the notion of a "safe minimum standard" to serve as the practical approximation of the optimum state of conservation for society. This "standard" is defined "in terms of conservation practices designed to avoid the critical zone." Since irreversibility is not, for these resources, the certain consequence of depletion, there is a social cost involved in maintaining the safe minimum standard. The cost may be viewed as an insurance premium against social stagnation and inflexibility.

This theory and the concepts developed in it are, perhaps, the most important single contribution of the book. Not only does it serve as a guide for much of the subsequent policy consideration, but it indicates that one group of resources has both special qualities and a strategic economic position, conditions which are a *sine qua non* for special conservation treatment.

Following this analysis, various means of implementing conservation policy are given consideration. This section concerns itself largely with those tools specifically designed for conservation (direct tools), the more general economic forces which may be used having been studied in the section on the private economics of conservation. Although developing in part from the theory just mentioned, it is of minor analytical interest, being in the nature of a thorough survey of the direct tools. This section is less imaginative than earlier parts of the book.

One aspect of the over-all analysis requires comment. The author's definition of conservation is given as the redistribution of use of a resource "in the direction of the future" (p. 51). Following this it is somewhat startling to find (p. 77) the definition of the optimum state of conservation for the private planning agent "as that time distribution of use rates that maximizes the present value of the flow of (expected) net revenues," and a similar definition (p. 230) of the optimum state of conservation for social policy in term of maximizing "social net revenues over time."

In developing these optimum concepts the author has made the decisive an determining factor *value*, an element which is notably absent from his defini tion of conservation. In view of this latter fact, it is not apparent *how*, no for that matter *why*, the maximization of present value (to either the privat planner or society) should be at the same time uniquely the optimum stat *of conservation*. The analysis shows no connection between value and con servation and certainly the definition given for conservation does not.

In moving from one criterion of conservation (time) to another (value the analysis avoids the thorny problems associated with explaining resourc valuation. Yet this is a fundamental aspect of any theory of conservation, fo unless there is something singular about a resource by reason of which societ cannot afford to value it as ordinary economic goods are valued in the marke

special conservation treatment—as distinguished from ordinary economizing—is irrelevant. The penalty this book pays for side-stepping the valuation problem is a loss of some degree of unity of topic and a certain loss of urgency of purpose. One is left with a feeling that the main battle about conservation was over before he picked up the book.

Another less significant observation is worth mentioning. Although the book makes some attempt to consider nonrenewable (stock) resources, its specific coverage of them is slight and the "general" conservation analysis is often too narrow to consider important factors related to their conservation. For example, total ultimate recovery of these resources is assumed at several points in the book to be a fixed stock which is insensitive to price. In fact, both current supply and ultimate recovery of such resources are characteristically functions of price.

Despite these drawbacks the work indicates many new tools for use in conservation policy and the manner in which they affect conservation decisions. The work of the author also results in the development of several new theories explaining resource characteristics and the effect of those characteristics on society. For these reasons the reviewer feels that the work is a distinct contribution to the literature on the economics of conservation.

JOHN C. MURDOCK

University of Missouri

Agricultural Prices. By FREDERICK LUNDY THOMSEN and RICHARD JAY FOOTE. 2nd ed. (New York: McGraw-Hill. 1952. Pp. ix, 509. $6.50.)

There are now three good textbooks on the subject of agricultural prices. F. L. Thomsen, the senior author of the text under review, pioneered in this field with his first edition of *Agricultural Prices* in 1937. The second edition, substantially revised, now competes, however, with Shepherd's *Agricultural Price Analysis* (1947) and Waite and Trelogan's *Agricultural Market Prices* (1951).

The new text is an improvement upon the original. Most chapters have been rewritten and up-to-date material has been included. Part I deals with Price Determination and Discovery, with specific reference to agricultural prices on the wholesale and retail level. This is first a simple presentation of price theory under conditions of perfect and imperfect markets and includes a brief discussion of aggregative price determinants in addition to the conventional demand and supply analysis. Furthermore it describes and analyzes the general behavior of prices over shorter and longer periods of time. Chapter 9 deals with the relation between cash and future prices and has been taken over almost unchanged from the first edition; it still remains a good description of the rôle which the future market plays, or is assumed to play, in agricultural marketing. Chapter 12 describes various price programs of the federal government which have become "one of the most important factors affecting commodity prices." The programs are largely appraised in the light of theoretical considerations of the free market model. Part II is devoted to the problem of handling price data for statistical analyses, for price forecast-

lating price data and of price analyses, such as index numbers, correlation analyses and long-run and short-run price variations. If used in undergraduate classes, these chapters would necessitate spending some time on statistics, in the absence of previous training in that field. Agricultural extension economists and county agents might find valuable material in the chapters dealing with the methods and difficulties of making price forecasts and outlook reports. In Part III, individual commodities and their prices are dealt with in some detail, such as hogs, beef, dairy products, cotton and wool. For each commodity the major demand, supply and other factors which determine prices are explained, and price behavior and analyses are described.

The main value of the book is that it furnishes further detailed material to enable students and others to understand the nature of price problems and price analysis—an understanding which is necessary for explaining and predicting prices, as well as for controlling them.

For those that like to have their economics shot straight from the hip, this book will be very satisfactory. The manner in which the various price problems have been integrated into a structure for which equilibrium theory serves as a basis commands respect. Examination of price problems, such as those encountered in connection with government price programs, is straightforward and technically well presented with a few minor exceptions. For instance, it would have been preferable if Figure 32 (p. 213) relating to the storage problems and showing hypothetical total return curves under conditions of "inelastic demand," had been drawn so as not to leave the impression that the entire range of the demand curve was inelastic.

The appraisal of government price programs by the authors suffers from occasional moralizing which could affect some readers or students in a manner entirely opposite to the one intended. It is one thing to explain and analyze the "forces interfering with the operation of a free economy" in the light of rigorous economics, but another to imply that those that challenge the conclusions of "sound" economics are necessarily "misguided."

One of the conclusions reached by the authors is that "with certain exceptions . . . retail food prices are determined largely under conditions of pure competition," while marketing margins, *i.e.*, prices received by marketing agencies for the service they perform are "rarely determined under conditions of pure competition" (p. 97). For this statement, there is however little evidence in the text. It seems somewhat contradictory in the light of the various types of imperfect competition—enumerated on the following pages—which we find at all levels of trade. Also, the chapter on pricing under imperfect competition fails to bring out pricing problems under monopsonistic situations which exist in the case of many agricultural commodities on the farm level.

Agricultural Prices, besides being an appropriate text for a special course in that field, is useful as complementary reading material for those that use textbooks in marketing which do not emphasize economic theory in relation to marketing problems (including F. L. Thomsen's *Agricultural Marketing*). For general economists, its value lies mainly in the application of economic theory to the analysis of policy problems.

Labor

Wages Policy under Full Employment. By E. LUNDBERG, R. MEIDNER, G. REHN and K. WICKMAN. Edited and translated by RALPH TURVEY. (London: Wm. Hodge & Co. Ltd 1952. Pp. viii, 88. $1.)

This is a collection of short essays by four Swedish economists on how to manipulate wages so as to permit the reconciliation of full employment with the prevention of inflation. Of the four only Lundberg, by virtue of his *Economics of Expansion* (London, 1937), will be familiar to American readers. Meidner[1] and Rehn are employed by the Swedish central labor organization, but are (or have been) associated with the Stockholm Business Cycle Research Institute, of which Lundberg is chief. Wickman, who has also worked at this institute, is identified, in the editor's two-page foreword, only as "a specialist in welfare economics."

The essays in question were originally published in Swedish; some in the Social Democratic monthly *Tiden* and the others in the professional (economic) journal *Ekonomisk Tidskrift,* between 1948 and 1950. Lundberg opens the book with a brief general discussion of the issues of wage level policy, and this is followed by Meidner's paper, "The Dilemma of Wages Policy under Full Employment." The bulk of the volume consists of Rehn's paper, "The Problem of Stability: An Analysis and Some Proposals"; a critique thereof by Lundberg and a rejoinder by Rehn. Wickman's very short essay concludes the volume.

It seems fairly clear from the discussion that Lundberg's general position is (by American standards) that of a moderate conservative. His critique of Rehn's proposals (designed to prevent inflation without sacrificing full employment) is marked by concern lest resources be misallocated; lest there be "insufficient risk-taking"; lest the "transfer [of] a large part of private saving to the State" involve an undesirable concentration of economic power; etc. He also argues that "it is very possible that some degrees less of full employment, secured by a restrictive credit policy and without price increases, might be more effective in stabilizing wages than increasing prices by indirect taxes."

The other contributors are all Social Democrats; however, their views imply differences of opinion on the correct wage policy to be recommended to the labor movement. Meidner's view, for example, is not too far removed from Lundberg's; he asserts that it is "excess monetary demand which is the real cause of over-payment, affecting both wages and prices." And his solution is to eliminate the "excess monetary demand." He does not state just how much unemployment he would accept in exchange for such elimination, but does indicate repugnance for "a relapse into a society of the insecure pre-war type." Although Meidner does not offer any guidance in how to get "full employment without inflation," his argument is an interesting Swedish expression of a desire to preserve the independence of unions from even a govern-

[1] Rudolf Meidner is the principal economist of the Swedish Labor Federation while Gosta Rehn is a member of his staff.

ment controlled by their allies. He believes that unionism's primary function is the determination of wages through collective bargaining and that failure to exercise this function by *individual* unions would cause "the members' desire for an interest in the organization [to] lag." Hence he disparages any notion of a centrally determined wage policy[2] and rejects the idea that unions should be "responsible" or "reasonable." The vehemence of his position may be surmised from the following: "There is no organization whose very existence is threatened to the same degree by this excess demand as is the trade union movement which must maintain its dominant position in the wage-formation process if it wants to survive."

Meidner's position is essentially that of the Trade Union leaders, anxious to preserve their independence of the government even when it is dominated by the Social Democrats. Rehn, however, is more willing to take the risks of living with Leviathan. Like Meidner, he believes that the unions cannot, for long, act to hold down wages in the presence of excess labor demand without losing their principal *raison d'être* (and membership). But while Meidner does not specify how he would eliminate excess demand, Rehn has an explicit proposal. He argues that full employment, under existing institutional arrangements, generates (unduly) "high profits," which in turn generates the excess demand for labor which (unions or no) puts upward pressure on wages. The crucial link in the chain between full employment and inflationary wage increases is high profits; and it is this link which Rehn proposes to break by a system of *indirect* taxes levied on "gross production" rather than profits. (Direct taxes are rejected because of their adverse effect on incentives.) Government revenues and expenditures are to be balanced at full employment equilibrium; part of the receipts, however, are to be earmarked for investment purposes and these receipts would be invested or sterilized as the exigencies of the situation required. Underemployment would be combatted by using the investment funds to give jobs to the idle and/or to subsidize certain firms incurring losses; inflation would be fought by sterilizing part or all of the revenues earmarked for investment. But in order to curb effectively both inflation and unemployment, the state "must be able to determine and direct the use of an increased share of the total National Income."

In short, Rehn proposes to transfer a part of profits to the state via indirect taxes. The new full employment equilibrium will involve smaller private, and larger public, investment than heretofore. Absence of high profits will, according to Rehn, remove the excess demand for labor that generates wage increases. But what if unions demand "excessive" wage increases anyway,

[2] This impression of Meidner's position is based on his essay as printed in the book. However, through Professor Walter Galenson, I have seen a mimeographed form of this paper (in English). The translation is virtually identical with Turvey's except that in Turvey's version certain important sentences are omitted from the next to last paragraph (p. 28). They include the following remark: "the trade union part of it has to be consolidated—by a further levelling of ungrounded wage differences, by intensified instruction and by a planned agreement policy, which would not exactly mean centralized actions for increased wages but central influence on the claims of the different unions." This remark quite alters Meidner's position as expressed in the book (making it much closer to Rehn's) it would be interesting to know why it was deleted.

relying on the implicit guarantee of full employment to save their members from unemployment? To circumvent this difficulty Rehn proposes a "centrally planned wage policy—on which the trades union movement can reasonably be asked to take responsibility." Such a policy implies that "the central body must support reasonable wage claims and check the less reasonable ones"; this wage policy will aim at equity among different groups of wage earners rather than encouraging each to bargain for all it is able to take. One consequence of this wage policy would be to narrow (interindustry) wage differentials. Rehn would permit small interindustry differentials to exist as a spur to the transfer of labor from less to more profitable industries; however, he does not think that such differentials (or those now existing) are a sufficient incentive for the optimal degree of mobility, and he therefore proposes government financed bounties (administered by labor exchanges) to induce workers to move into certain designated expanding industries.

One obvious difficulty with Rehn's program relates to his assumption that unions will refrain from demanding "inflationary" wage increases in the presence of full employment if there is a transfer of "excess" business profits to the Treasury via indirect taxes. Both Lundberg's critique and Wickman's essay express doubts on this matter, doubts shared by the reviewer. A second difficulty, also noted by Lundberg, is our ignorance of how much government investment (or subsidies) would be required to maintain full employment under Rehn's scheme. The amount could vary enormously depending upon business response to the initiation of the plan. Rehn's rebuttal to these arguments is not, in my opinion, satisfactory: despite the admirable restraint of the Swedish unions in recent years, it is at least debatable that, even in Sweden, this could continue indefinitely. In any event, the matter requires more discussion than Rehn devotes to it. The second difficulty is not really considered at all; at bottom, I suspect, Rehn is not overly worried about "too much" government investment.

On the other hand, Lundberg's position is not a happy one: to argue for credit restriction and "some degrees less of full employment" is to invite Rehn's retort, "less than what?" The cost of price stability in terms of unemployment is simply not known. Rehn's rebuttal further argues that, while his own proposal may not be perfect, it is superior to the mixture of direct controls and exhortation that has characterized much of postwar wage policy in Sweden and elsewhere. And it is not clear that Lundberg would not choose Rehn's proposal rather than continue existing policies. Lundberg's *attitude* is clear; he would like somewhat more stress on curbing inflation and somewhat less on maintaining full employment, but it is by no means easy to translate this *attitude* into a positive *program*.

By and large, these essays are well worth the attention of students of wage policy. They do not take us very far beyond the discussions of English-speaking economists, but there are certain differences of emphasis that justify a reading. It is unfortunate that the editor did not provide an introductory essay on the political and economic situation that gave rise to the debate and a description of the relevant Swedish institutions. It is only inferentially that

the phenomenon of the "wage stops" (freezes) in Sweden enter the discussion; yet these are basic to any understanding of the practical bearing of the argument. Again, the background of the "solidaristic" wage policy that has (over the past two decades) narrowed wage differentials, and upon whose acceptance Rehn's proposal rests, is not considered. An explanation of such phenomena as these would have added greatly to the value of the book. But beggars cannot be choosers and, as it is, Turvey has left us in his debt.

Sidney Hillman, Statesman of Labor. By Matthew Josephson. (New York: Doubleday and Co. 1952. Pp. 701. $5.00.)

Matthew Josephson's biography of Sidney Hillman could hardly fail to be an interesting and absorbing study. The man, the union he represented, their joint rôle in the growth of the American labor movement, are such vital parts of our recent history that attention is inevitably drawn to what Josephson has to say. But oddly enough, although one's interest is maintained throughout the study, this reader was left disappointed. Despite Josephson's generally recognized skill as a writer, the personality of Hillman fails to emerge in convincing fashion. We are told repeatedly that Hillman was a great labor leader and statesman, but still the reader is left with the feeling that adequate demonstration is lacking. After nearly 700 pages of text Hillman remains a largely unknown character—Josephson's adulation notwithstanding. It is hard to account for this failure. Although Hillman left few personal records, a considerable number of people who knew him well (including his wife) were available to the biographer. Many, indeed, are quoted in their appraisal of Hillman—with some bias towards those who admired him most—while less attention is paid to Hillman's critics, most notably David Dubinsky.

The biography follows a rather straightforward chronological pattern starting with a brief account of Hillman's youth in Russia where he participated in the revolutionary movement. His changeover from a revolutionary to a moderate trade union leader after his immigration in 1907 is certainly not adequately explained by Josephson. The best told parts of the story cover the turbulent years from 1910 when Hillman first joined the United Garment Workers Union, after working for a relatively short time as a cutter in Chicago, until 1914 when, at the age of 27, he became president of the new Amalgamated Clothing Workers Union. But even this part of the history cannot be accepted uncritically. One of the great difficulties faced by a biographer is to resist the temptation to let the hero steal the show. Josephson does not entirely succeed. So in the early years the parts played by such workers as Joseph Schlossberg, Hyman Blumberg, August Bellanca and Bessie Abramowitz (later Mrs. Hillman) receive a smaller share of the spot-light then they deserve. And some will question whether Hillman would have risen to the leadership of the union without the active sponsorship of such off-scene workers as the arbitrator John E. Williams, the social worker Jane Addams and the lawyer Clarence Darrow. Similarly, in the later period, as during the

formation of the CIO, the rôle of John L. Lewis is certainly underplayed.

For the economist the omissions that will be most noticed concern the changing economic status of the clothing workers. Since World War I, the Amalgamated Clothing Workers Union in varying degree has exercised considerable influence, through unionization, in the men's outerwear industry. There is no attempt made by Josephson to follow up in any systematic fashion the consequences of unionization in such important areas as wages, employment or migration of the industry. Much attention is paid to strikes and to the extention of union control and mention is made of the union's efforts to aid the industry along the lines of "scientific management." But in fact the reader will learn more about such fringe issues as the Amalgamated Bank and cooperative housing sponsored by the ACWU than he will about what actually happened to the workers in the industry. To cite one example, in 1923 about 63 per cent of all employment in the men's outerwear industry in the United States was found in six cities, where the union had its greatest control (although the degree of unionization was not equal in all these cities). By 1937 the comparable figure had fallen to 49 per cent, a decline of 14 percentage points. In Chicago alone, the original stronghold of the union, the employment percentage fell from 18 to 8 per cent of the national total between 1923 and 1937. Josephson makes no attempt to set forth these important developments, which are well known and uncontested facts; and consequently he fails to probe into some of the most vital problems of the industry which fostered Sidney Hillman and which was, in turn, molded in a significant fashion by him.

CARRIE GLASSER ABRAMOVITZ

Palo Alto, California

AFL Attitudes Toward Production, 1900-1932. By JEAN TREPP MCKELVEY. Cornell Studies in Industrial and Labor Relations. Vol. II. (Ithaca: Cornell Univ. Press. 1952. Pp. ix, 148.)

This volume represents the interpretative part of a doctoral dissertation on union-management cooperation written by the author two decades ago at Radcliffe College. The dissertation material describing actual cases of cooperation, since then covered by other writers, has been omitted from the publication.

Professor McKelvey's interpretation of the development of a "cooperating philosophy" by the American Federation of Labor during the period in question is essentially this: The weakness of the labor movement, stemming from various socio-economic conditions, prompted union initiation of cooperating ventures as a technique for the survival and growth of trade-unionism. In her own words:

> . . . the difficulties involved both in overcoming the apathy of the workers and in forcing recognition from employers suggested that the easier road to organization lay in selling the union to employers by persuading them that their own self interest could best be promoted through union recognition, that the trade union alone, in contradistinction to the com-

> pany union or other forms of employee representation, could supply the broad basis of confidence necessary to release the full productive energies of the workers (p. 119).

But this cooperating "philosophy" did not emerge automatically. Quite the contrary,

> . . . leadership is necessary to analyze a new industrial situation and to formulate a program for dealing with it. Leadership is also essential in educating the rank and file to acceptance of policies which involve a departure from long established procedures. So far as the AFL is concerned, there is little doubt that William Green was the person chiefly responsible for its support of union-management cooperation (p. 120).

The author emphasizes, however, that the cooperating technique failed to attain the objectives of organized labor.

Union-management cooperation designed to increase productivity—which is the sense in which the author uses the term—is characterized (among other things) by a spotty growth pattern: At any given time it will exist in some bargaining units (or subdivisions thereof) and not in others; and it does not continue indefinitely in those units where it emerges. Given this fact, it is neither realistically constructive nor analytically accurate to deal with the problem of cooperation by pitching the approach at the level of the entire economy and focusing on federation leadership, as did Professor McKelvey. Instead, the investigation must be oriented toward the particular business units where the cooperating ventures are being tried and toward the labor leadership relevant to those units. In some instances this may mean focusing on the "philosophy" of an obscure local official, in others on a national labor figure, in still others on a regional director, etc. And such a research dictate is reinforced by the fact that the component national unions of the AFL are nigh-perfect autonomous bodies when it comes to elaborating and executing collective bargaining policies. Nor should one fail to note that within many of these nationals, some or all of the locals themselves have a great deal of autonomy where job problems are concerned.

All this is not to imply, of course, that the "philosophy" of the AFL leadership is of absolutely no importance for the success or failure of union-management cooperation experiments, either during the period studied by the author or a different time span. But compared to the other forces impinging on the national, and particularly the local, union officials in America, the impact of so-called Federation viewpoints and attitudes is relatively negligible.

This reviewer is not asserting that by any stretch of the imagination is adequate local or national union leadership enough for the successful emergence and continuation of union-management cooperation plans. There are various other conditions that must be fulfilled. But to ascertain *concretely and operationally* what these conditions are, the researcher must concentrate his investigations on the relevant business units. That again points up the fact that to deal with the cooperation problem at the level of the entire economy, which the author has done in this volume, is of relatively little practical value. It may well be, of course, that in her doctoral dissertation she did make

exhaustive case studies of the particular plans that were initiated during the 'twenties. But if so, her analysis and interpretation in this volume should have focused on these particularities.

This reviewer has evaluated the study from the vantage point of a "pragmatist" (in the philosophical sense). That in no way, however, implies a similar evaluation of Professor McKelvey's effort in the light of other criteria. For instance, as a chapter on the "intellectual" development of certain segments of the AFL leadership during the 'twenties, this monograph might well prove a noteworthy document. And the reader should also keep in mind that the study was completed twenty years ago, when the techniques and insights now commonplace were unavailable.

University of Buffalo

The Organizability of Farm Labor in the United States. By ALEXANDER MORIN. (Cambridge: Harvard University Press. 1952. Pp. 102. 50 c.)

For many years the problems and difficulties of organizing field workers in agriculture have been known. But the author is perfectly right when he states that "there has been little or no systematic analysis of the specific problem of the organizability of the farm wage worker." To fill this void is the object of this monograph.

The central observations of the study may be summarized as follows: the problem of union organization in agriculture, as compared with industry, is more complex than are suggested by the purely economic and operational factors of organizability; in contrast to industry, the psychological barriers to successful unionism in agriculture (farm worker identification "with farm-owning or with non-agricultural groups") are more formidable; the hope of escaping from wage employment in agriculture overrides the typical worker's concern about conditions on the job, and hence "the remedial efforts of farm worker trade unions" are of secondary importance; and joining a union of his fellow farm workers is not the path pointing to his long-term aspirations.

A glance into the past makes it difficult to confute these observations. And a look at the present does not raise doubts as to their general validity, but it does raise the question: How really crucial or significant are these difficulties when it comes to organizing hired farm workers into stable unions? Although it is true, as Mr. Morin states, that "a recognition of permanence in farm work will contribute to future organizing campaigns," too much may be made of this point. What must not be lost sight of is the fact that at least two million workers try to make a living mostly from wage employment in agriculture every year. And this suggests a sizeable gross organizable potential for many years to come. With organizational perspectives trained on the short rather than on the long occupational horizons of agricultural hired workers, it is conceivable that appropriate techniques can be devised to meet the organizational problem of excessive occupational turnover among these workers.

As for the economic and operational factors affecting union organization in

agriculture, none is more important than the character of the farm labor market itself. In this respect, Morin does a very creditable job, particularly in describing the labor supply aspects of this market. Because easy entrance into seasonal farm work tends to undermine the employment opportunities of those workers more or less permanently attached to agriculture, it is both a principal incentive and a major difficulty in their organization. Not mentioned, however, is that one of the most important factors in preventing unionization of large-scale agriculture in the Southwest, for example, is the current legal and illegal employment of Mexican nationals.

At one point Morin states that "dispersion [of employment] is no doubt one of the principal reasons for the failure of hired farm workers to organize into unions." This largely begs the question. Union policies and practices have not embraced the nation as a whole, but only those areas characterized by employment of comparatively large numbers of workers per farm establishment. One wonders whether, in the final analysis, the psychological and operational problems associated with organizing farm laborers are so tough or so unique that they could not be overcome by a resourceful and determined leadership having a budget of, say, one-half million dollars a year for a minimum of five years for organizational work in the most concentrated areas of farm employment. There is no question but that this budget would have to be underwritten largely by unions operating in urban or semi-urban occupations.

Although this study has the limitations to be expected of any first effort at a systematic analysis of the problem, it is a contribution to the understanding of why the last major unorganized sector of our economy has not been unionized.

Population; Social Welfare and Living Standards

Consumer Problems. By Aach W. Troelstrup. (New York: McGraw-Hill. 1952. Pp. xv, 458. $4.75.)

This book is intended to be a practical aid for people setting up housekeeping. It is doubtful that Professor Troelstrup intended the book to add anything new to the science of economics or to sociology. The foreword states that the book was developed in a consumer problems course at Stephens College.

There are many students, however, who either are, or think they are, too sophisticated for the style of this book. Students at a large urban university, for example, may consider that it has been "written down" to them. At some colleges elementary economics is a prerequisite for the consumer economics course and this book is not advanced enough for such a course.

Consumer Problems cannot be classified as a book in the economics of

consumption, or family finance, or marriage and the family. It cuts across all three fields. Most consumer texts, such as those by Coles, Reid, Waite and Cassady, Hoyt, Vaile and Canoyer, Campbell, or Gordon try to use the problem approach as a springboard to deal with issues of broader significance. Such texts relate shopping to the problem of making consumer demand effective in the market. Budgeting is subordinated to a study of income and expenditures, national and average rather than imaginary and personal. Troelstrup, in contrast, quotes the Heller Committee budgets for San Francisco families of four persons (an executive with a budget of $12,849.24 before rent; a white collar worker with $5,208.47 excluding housing; a wage earner, $4,111.22) without indicating to what families these budgets may be applied except for the information contained in the budget titles. The U. S. Bureau of Labor Statistics budget for a city worker's family of four persons (1947) is given but there is no discussion of the incomes of city workers' families.

A few examples may show the kind of useful information which the book contains. The chapter on food shopping has good material on grades similar to that in Coles' *Standards and Labels for Consumers' Goods* (1949). The chapter on savings, also, has an intelligent discussion of insurance. It implies, however, that financial security can be achieved by good savings and insurance programs. It seems almost useless to teach the student to plan his personal financial life so carefully without stressing the limits to this kind of planning. Much that will happen to the student financially will depend upon the economy as a whole—the stage of the business cycle, peace or war, the kind of taxes levied, the relative distribution of income, the general level of prices, and the relative levels of different prices. Subject to these developments the individual may labor to balance his budget and achieve financial security.

Economic Theory; General Economics

BAIN, J. S. *Pricing, distribution and employment: economics of an enterprise system.* Rev. ed. (New York: Henry Holt. 1953. Pp. xvii, 732. $6.50.)

The revised edition includes "a more comprehensive chapter on demand (including added material on the theory of consumer choice)," more attention to the "welfare impacts of competitive and monopolistic pricing," a substantially rewritten treatment of oligopolistic pricing, and a new chapter on the theory of price discrimination. "The conventional theory of income distribution, as developed on certain simple equilibrium assumptions, is now presented without interruption in the three chapters following the section on price theory, while the theory of income and employment, together with an analysis of interest and other distributive shares under nonstationary conditions, follow."

RAISTRICK, A. *Dynasty of ironfounders: the Darbys and Coalbrookdale.* (New York: Longmans, Green. 1953. Pp. xvi, 308. $8.50.)

The story of a business concern from the time of its founding, at the end of the 17th century, to the present.

SCHLOTE, W. *British overseas trade from 1700 to the 1930's.* Trans. from the German by W. H. Chaloner and W. O. Henderson. (New York: Macmillan. 1953. Oxford: Basil Blackwell. 1952. Pp. xvi, 181. $4.50.)

The German edition of this work appeared in 1938. The editor of that edition said in his introduction that the book "aims at tracing the development of British overseas trade and its changes within as long a period as possible." The book falls into two parts: "The first deals with the sources and methods of the research and tabulates the results. The second part (based upon the evaluation of the statistical material) shows structural economic changes by analysing the growth of overseas trade. These changes have affected both the composition of the goods entering into overseas trade and also the geographical complexity of British overseas trade during the last 120 years."

SHEPARD, W. F. *Price control and the reign of terror: France, 1793-1795.* History pub. vol. 45. (Berkeley and Los Angeles: Univ. of Calif. Press. 1953. Pp. 139.)

MAXIMOFF, G. P., ed. *The political philosophy of Bakumin: scientific anarchism.* (Glencoe, Ill.: The Free Press. 1953. Pp. 434. $6.)

A compilation, in systematic arrangement, of excerpts in English from Bakumin's works.

NAIK, K. N. *The co-operative movement in the Bombay state.* Vol. 19 Indian Econ. Stud. edited by C. N. Vakil. (Bombay: Popular Book Depot. 1953. Pp. xiv, 282. Rs. 10-8.)

SEELY, C. S. *Philosophy and the ideological conflict.* (New York: Philosophical Lib. 1953. Pp. 319. $5.)

The history of Materialism in its struggle with Idealism, going back to early times. Modern Materialism, based on Marx, is examined in the latter half of the book, and there are chapters on its applicability to the fields of politics, economics, sociology, and religion. It is a principal thesis of the book that Capitalism (supported by Idealism) is gradually losing the battle with Socialism (supported by Materialism).

STEIN, G. *The world the dollar built.* (London: Dobson. 1952. Pp. 288. 12*s.*, 6*d.*)

NOTES

SIXTY-SIXTH ANNUAL MEETING OF THE AMERICAN ECONOMIC ASSOCIATION

Hotel Statler, Washington, D.C., December 28-30, 1953

Preliminary Announcement of the Program

All the sessions of the program deal in some way with the changing structure an functioning of the American economy. Most of the sessions are concerned also with th problem: What are the economic principles which characterize the behavior of an econom of large-scale business units, large labor unions and a considerable degree of goverr mental intervention and control, but with old and new forms of competition neverthele playing a strategic role?

Monday, December 28

10:00 A.M. Meeting of the Executive Committee
12:00 M. Luncheon Meeting of the Executive Committee
2:30 P.M. FUNDAMENTAL CHARACTERISTICS OF THE AMERICAN ECON OMY: DEGREES OF COMPETITION, OF MONOPOLY AND O COUNTERVAILING POWER: THEORETICAL SIGNIFICANCE

Chairman: EDWARD H. CHAMBERLIN, Harvard University
Papers: Countervailing Power, A Moderate Defense of a Modest Innovatio
J. K. GALBRAITH, Harvard University
The Economist Plays With Blocs
GEORGE J. STIGLER, Columbia University
Competitive Processes in the American Economy
JOHN P. MILLER, Yale University
Discussion: DAVID MCCORD WRIGHT, University of Virginia

AN APPRAISAL OF ECONOMIC CHANGE

Chairman: MILTON S. HEATH, University of North Carolina
Papers: Twentieth Century Entrepreneurship: An Appraisal of Econom Change
ARTHUR H. COLE, Harvard University
The Changing Structure of Market Competition
ROSS M. ROBERTSON, Federal Reserve Bank of St. Louis
Discussion: FRANK H. KNIGHT, University of Chicago
ANDREAS PAPANDREOU, University of Minnesota

INSTITUTIONAL ASPECTS OF SAVING AND INVESTMENT

Chairman: LESTER V. CHANDLER, Princeton University
Papers: The Structure of the Market and the Price of Money
WALTER A. MORTON, University of Wisconsin
The Institutional Saving-Investment Process and Current Econom Theory
JAMES J. O'LEARY, Life Insurance Association of America
Monetary Policy and the Structure of Debt
E. S. SHAW, Stanford University
Discussion: SUSAN S. BURR, Board of Governors of the Federal Reser System

8:30 P.M. FACTOR MARKETS VS. PRODUCT MARKETS; IS THE AMERICAN ECONOMY MORE COMPETITIVE IN THE LONG RUN THAN IN THE SHORT RUN?

Chairman: KENNETH E. BOULDING, University of Michigan

Papers: Monopolistic Forms and Competitive Accomplishments
G. WARREN NUTTER, Yale University
Resource Allocation in the United States
ARNOLD C. HARBERGER, University of Chicago

Discussion: SYDNEY ALEXANDER, Columbia Broadcasting Company
RUTH P. MACK, National Bureau of Economic Research
JOE S. BAIN, University of California

DIMINISHING INEQUALITY IN PERSONAL INCOME DISTRIBUTION; RELATION TO FUNCTIONAL DISTRIBUTION AND FACTOR COMPENSATION

Chairman: WASSILY LEONTIEF, Harvard University

Papers: Economic Implications of the Declining Inequality in Income Distribution
GEORGE GARVY, Federal Reserve Bank of New York
On the Process of Income Distribution
ROBERT M. SOLOW, Massachusetts Institute of Technology

Discussion: ALLAN M. CARTTER, Duke University
SELMA F. GOLDSMITH, Department of Commerce

TECHNOLOGICAL PROGRESS AND ECONOMIC INSTITUTIONS

Chairman: ROBERT CALKINS, The Brookings Institution

Papers: The Conditions of American Technological Progress
IRVING H. SIEGEL, Twentieth Century Fund
Innovations and the Size of the Firm
W. RUPERT MACLAURIN, Massachusetts Institute of Technology

Discussion: WALTER ADAMS, Michigan State College
HANS BREMS, University of California
VINCENT F. BOLAND, JR., University of Arizona

Tuesday, December 29

9:30 A.M. INDUSTRIAL PRICING; INSTITUTIONAL PRACTICES VS. ABSTRACT MODELS

Chairman: EDWARD S. MASON, Harvard University

Papers: A Theory of Industrial Markets and Prices
RICHARD B. HEFLEBOWER, Northwestern University
Concepts of Value Theory: Their Operational Significance and Validity
RICHARD RUGGLES, Yale University

Discussion: JESSE MARKHAM, Vanderbilt University
VERNON MUND, University of Washington
HENRY M. OLIVER, Indiana University

FARM PRICES AND FARM INCOMES IN AMERICAN AGRICULTURE: IS AMERICAN AGRICULTURE STILL ESSENTIALLY COMPETITIVE AND LAISSEZ-FAIRE? (Joint Session with American Farm Economic Association)

Chairman: WILLIAM NICHOLLS, Vanderbilt University

Papers: The Impact of Government Programs on Farm Incomes
M. R. BENEDICT, University of California
Competition In Agriculture: Fact or Fiction
GALE JOHNSON, University of Chicago

Discussion: O. V. WELLS, Department of Agriculture
GLEN L. JOHNSON, Michigan State College

WAGE DETERMINATION IN THE AMERICAN ECONOMY; POTENTIALITIES AND LIMITATIONS IN THE USE OF COLLECTIVE ECONOMIC POWER IN VARYING THE COMPENSATION OF LABOR AND CAPITAL

Chairman: John T. Dunlop, Harvard University
Papers: Collective Bargaining and Distributive Shares
CLARK KERR, University of California
The Incidence of Collective Bargaining
MARTIN BRONFENBRENNER, University of Wisconsin
Collective Bargaining and Income Distribution
HAROLD M. LEVINSON, University of Michigan
Discussion: JOHN P. TROXELL, Stanford University

12:30 P.M. LUNCHEON MEETING: Joint session with the American Finance Association
Speaker: W. Randolph Burgess, Treasury Department

2:30 P.M. ALTERNATIVE POSSIBILITIES OF INFLATIONARY PRESSURES AND HIGHER COST BOTTLENECKS IN AN ECONOMY OF LARGE BARGAINING UNITS AND OF LESS THAN PURE AND PERFECT COMPETITION IN THE MARKETING OF PRODUCTS

Chairman: To be announced
Papers: Are Wage Fixing Arrangements in the American Labor Market Inflationary?
SUMNER SLICHTER, Harvard University
C. L. CHRISTENSON, Indiana University
Discussion: ALBERT REES, University of Chicago
CLARENCE E. AYRES, University of Texas
LORIE TARSHIS, Stanford University

THE ROLE OF CORPORATE TAXATION IN THE AMERICAN ECONOMY

Chairman: ROY BLOUGH, United Nations
Papers: The Corporation and Corporate Taxation in the American Economy
GERHARD COLM, National Planning Association
The Corporation Income Tax and Management Decisions (Joint Paper)
KEITH BUTTERS and JOHN LINTNER, Harvard University
Discussion: B. U. RATCHFORD, Duke University
MABEL NEWCOMER, Vassar College

NATIONAL TRANSPORTATION POLICY

(This session is being arranged by E. W. Clemens, University of Maryland, for the Transportation Group)
Chairman: To be announced
Papers: Regulatory Standards for a Sound Transportation Policy
CHARLES L. DEARING, The Brookings Institution
Promotional Standards for a Sound Transportation Policy
SIDNEY L. MILLER, University of Pittsburgh
Discussion: GEORGE P. BAKER, Harvard University
LIONEL W. THATCHER, University of Wisconsin

INDUSTRIAL CONCENTRATION: Joint Session with American Statistical Association •

8:30 P.M. PRESIDENTIAL ADDRESS: ECONOMIC IMPLICATIONS OF INSTITUTIONAL CHANGES IN THE ECONOMY

CALVIN B. HOOVER, Duke University
Chairman: To be announced

Wednesday, December 30

ECONOMIC DOCTRINES IMPLIED IN THE REPORTS OF THE UNITED NATIONS AND OF THE INTERNATIONAL BANK FOR RECONSTRUCTION AND DEVELOPMENT ON UNDERDEVELOPED COUNTRIES

Chairman: PAUL T. ELLSWORTH, University of Wisconsin
Papers: Economic Doctrines Reflected in United Nations Reports
RAYMOND F. MIKESELL, University of Virginia
Economic Development; Theory and Practice à la I.B.R.D.
JOSEPH J. SPENGLER
Discussion: WILFRED MALENBAUM, Massachusetts Institute of Technology
THEO SURANYI-UNGER, Syracuse University

REGIONAL WAGE DIFFERENTIALS IN AN ECONOMY OF LARGE BARGAINING UNITS AND LESS THAN PURE AND PERFECT COMPETITION IN THE MARKETING OF PRODUCTS

Chairman: H. GORDON HAYES, Tulane University
Papers: Interregional Competition
SEYMOUR E. HARRIS, Harvard University
Geographical Wage Differentials and the Public Interest
JOHN V. VAN SICKLE, Wabash College
Discussion: WALTER ISARD, Harvard University
J. FRED HOLLY, University of Tennessee
LOUIS B. PERRY, Pomona College

THE AUTOMATICITY OF FULL EMPLOYMENT UNDER THE ASSUMPTION OF DIMINISHED DEFENSE EXPENDITURES

Chairman: To be announced.
Papers: Means Available for Checking and Reversing a Business Recession
ALBERT G. HART, Columbia University
Changes in Defense Expenditures and the Problem of Deflation: Some Possibilities and Methods of Control
GEORGE H. HILDEBRAND, University of California
Full Production or Under-Utilization: Appraisal of Long-Run Factors Other Than Defense
WILLIAM FELLNER, Yale University
Discussion: CLARENCE PHILBROOK, University of North Carolina
KENNETH D. ROOSE, Oberlin College

2:30 P.M. CORPORATE INTERNATIONAL INVESTMENT POLICIES AND PROGRAMS

Chairman: J. B. CONDLIFFE, University of California
Papers: Corporate Direct Investment Abroad Versus Portfolio Lending
AUGUST MAFFRY, Irving Trust Company
FRANCIS MCINTYRE, California-Texas Oil Co. Ltd.
Discussion: VINCENT W. BLADEN, University of Toronto
H. J. DERNBERG, Federal Reserve Bank of New York

ECONOMIC AND REGULATORY PROBLEMS OF THE BROADCASTING INDUSTRY

(Program arranged by E. W. Clemens, University of Maryland, for the Public Utilities Group)

Chairman: To be announced
Papers: Current Economic and Regulatory Problems of the American Radio and Television Industries
H. H. GOLDIN, Federal Communications Commission

The Development of British Television Service
RONALD H. COASE, University of Buffalo
Discussion: SIDNEY S. ALEXANDER, Columbia Broadcasting System
PETER O. STEINER, University of California

THE THEORY OF INTERNATIONAL TRADE IN A WORLD OF TRAD] BARRIERS AND CONTROLS AND OF VARIEGATED NATIONA] ECONOMIC SYSTEMS
Chairman: JOHN H. WILLIAMS, Federal Reserve Bank of New York
Papers: The Relevance of Classical Theory Under Modern Condition
GOTTFRIED HABERLER, Harvard University
Forces of Disequilibrium in International Trade
DON HUMPHREY, Duke University
Discussion: JOHN H. ADLER, International Bank for Reconstruction and De velopment
RICHARD M. BISSELL, JR., Massachusetts Institute of Technolog
G. A. ELLIOTT, University of Toronto

5:00 P.M. Business Meeting
6:00 P.M. Dinner—Executive Committee
8:30 P.M. GROWTH DECISIONS IN THE AMERICAN ECONOMY
Chairman: To be announced
Papers: To be announced
EDGAR M. HOOVER
Collective Bargaining and Economic Growth
JOSEPH SHISTER, University of Buffalo
Discussion: To be announced

ECONOMICS IN GENERAL EDUCATION—Round Table
Chairman: BEN W. LEWIS, Oberlin College

Participants:
S. P. MCCUTCHEON, New York University
CLARK ALLEN, Florida State College
E. T. WEILER, Purdue University

ECONOMIC IMPLICATIONS OF AN AGING POPULATION
(This session will consist of a progress report and an analytical review of tl research project being carried on by the University of California Institu of Industrial Relations under a grant from the Rockefeller Foundatioı
Chairman:
Papers: The Relation Between Age and Economic Status
MELVIN REDER, Stanford University
The Size, Nature and Adequacy of The Resources of the Ag
PETER STEINER, University of California
Aging and the Aged in Relation to the Labor Force
ROBERT DORFMAN, University of California
Discussion: FLOYD A. BOND, Pomona College

Doctoral Dissertation Titles

The United Nations Educational, Scientific and Cultural Organization has published *Theses in the Social Sciences.* The material has been collected from more than twenty states, including Australia, Austria, Belgium, Canada, China, France, India, Italy, Netherlands, New Zealand, Switzerland, United Kingdom and the United States of America. In the case of the last-mentioned country, the Department of State forwarded to UNESCO a selected list of doctoral dissertations for 1948-49 dealing with foreign countries and international problems. (In the case of the U.S.A. more complete coverage is now provided by *Doctoral Dissertations Accepted by American Universities,* compiled annually by the Association of Research Libraries, New York. This volume covers the natural sciences and humanities as well as the social sciences. Attention is also drawn to *Dissertation Abstracts* which is published six times a year by University Microfilms, Ann Arbor, Mich., and which provides titles and short abstracts of dissertations in all fields accepted by about thirty U. S. institutions of higher learning. Readers of this *Review* are also acquainted with the annual list of doctoral dissertations in economics that regularly appears in the September number.)

Committee on Economics in Teacher Education

An American Economic Association Committee on Economics in Teacher Education has been named to work with the recently formed Commission on Economics in Teacher Education. The Commission, sponsored by the Joint Council on Economic Education and working in cooperation with a number of professional associations, is undertaking to explore and promote ways of making economics a functional part of general education for future teachers. The Committee is organizing a round table on "Economics in General Education" for the Christmas meetings. It is hoped that this may be a first step in focusing the talents and energies of those members of the Association who have an interest in improving the teaching of economics in the secondary schools. The members of the Committee are Archibald McIsaac, Horace Taylor and Ben Lewis, chairman.

Everett Eugene Edwards Memorial Awards

The Agricultural History Society has established two annual awards, to be known as *The Everett Eugene Edwards Memorial Awards,* to be given to the authors of the two best articles (presidential addresses excluded) published in *Agricultural History* in each year. One prize of $50.00 is to be assigned to an author who is in course of taking a degree and one prize of $50.00 to an author who is a more advanced scholar.

Deaths

Lucile Eaves, professor emerita of Simmons College, died January 20, 1953.

Paul A. Fischer, U.S.N.R., retired and former government economist, died March 28, 1953.

Sylvia Wiseman has been appointed lecturer in economics at McGill University for t current session.

William B. Wolf has been appointed research associate in the School of Business of t University of Chicago.

F. E. Wolfe, of the Procter and Gamble Company, served as visiting professor at t University of Kentucky in the 1953 spring term.

Henry E. Wrapp has been promoted to associate professor of production in the Sch of Business of the University of Chicago.

David McC. Wright has been granted leave by the University of Virginia for the cı rent session to be a Fulbright professor of economics at Oxford University.

FIFTIETH LIST OF DOCTORAL DISSERTATIONS IN POLITICAL ECONOMY IN PROGRESS IN AMERICAN UNIVERSITIES AND COLLEGES

The present list specifies doctoral degrees conferred during the academic year terminating June 15, 1953, and theses undertaken in the same period. In the latter category the year following the dissertation title is the probable date of completion.

Economic Theory; General Economics

Degrees Conferred

HESHMAT ALA'I, Ph.D. Georgetown 1953. Theory of income distribution under the Islamic law with special reference to the function of residual income recipients.

ROBERT L. ALLEN, Ph.D. Harvard 1953. Agglomeration and spatial patterns in location analysis.

JAMES W. BECK, Ph.D. Iowa 1953. A macroeconomic approach to distribution theory.

GEORGE K. BRINEGAR, Ph.D. Chicago 1952. Short run income-expenditure relationships.

JOE E. BROWN, Ph.D. Texas 1953. The influence of population theory on the development of economic thought.

HUA-CHANG CHOW, Ph.D. Chicago 1952. The influence of interregional commodity and factor movement on the distribution of income.

JERE W. CLARK, Ph.D. Virginia 1953. Intercommunity commodity flows within the United States.

ALFRED W. COATS, Ph.D. Johns Hopkins 1953. Methodological controversy as an approach to the history of American economics, 1885-1930.

DANIEL R. FUSFELD, Ph.D. Columbia 1953. Economic thought of Franklin D. Roosevelt to 1932.

FRANCIS C. GENOVESE, Ph.D. Wisconsin 1953. A going concern theory of profits.

JOHN B. GLASSBURNER, Ph.D. California 1953. The social economics of Alfred Marshall.

EDWARD E. LECLAIR, JR., Ph.D. Clark 1953. Economic value in non-literate cultures: a cross-cultural reorientation in the theory of value.

ERWIN E. NEMMERS, Ph.D. Wisconsin 1953. Hobson and under-consumption.

MARTIN SEGAL, Ph.D. Harvard 1953. Some economic aspects of adjustment to technological change.

MARTIN SHUBIK, Ph.D. Princeton 1953. Competition and the theory of games.

MAUNG TUN THIN, Ph.D. Harvard 1953. Theory of markets.

CLEMENS B. THOMAN, Ph.D. Texas 1953. Capital—formation theory in transition.

WALTER C. WAGNER, Ph.D. Texas 1953. The theory of economic equilibrium: a reflection of social reciprocity.

WILLIAM R. WATERS, Ph.D. Georgetown 1953. Entrepreneurship, dualism and causality: an appreciation of the work of Joseph A. Schumpeter.

RICHARD S. WECKSTEIN, Ph.D. Yale 1953. The influence of the rate of interest on personal saving.

J. C. WELDON, Ph.D. McGill 1952. Theory of distribution.

LIST OF DOCTORAL DISSERTATIONS

Theses in Preparation

MARTIN J. BAILEY, B.A. California (Los Angeles) 1951. The general equilibrium tions of monetary theory. 1954. *Johns Hopkins.*

GARY S. BECKER, B.A. Princeton 1951. Discrimination: a theoretical and statistic 1954. *Chicago.*

Business Administration

Degrees Conferred

JEAN R. ANDERSON, Ph.D. Harvard 1953. The marketing of non-food products in Puer Rico.

JESSE B. ALLEN, Ph.D. Chicago 1952. A comparison of the marketing of alcoholic beve ages under state monopoly and open license systems.

JIM G. ASHBURNE, Ph.D. Texas 1953. Accounting reports for financial and operati management (a study of practices in the petroleum industry).

ALTON W. BAKER, Ph.D. Ohio State 1952. An analysis of personnel management in select small industrial plants in Ohio.

E. ROBERT BARLOW, D.C.S. Harvard 1953. Management and control of foreign subsi aries.

DILLARD E. BIRD, Ph.D. Ohio State 1953. The relation of stabilization within the busin organization to guarantees of work or wages.

GRANT H. CALDER, D.C.S. Indiana 1953. Some problems of selected small family-co trolled manufacturing businesses.

VEN-KAI (VICTOR) CHOU, Ph.D. Wisconsin 1952. An analysis of the applicability a effectiveness of retail profit sharing.

C. ROLAND CHRISTENSEN, D.C.S. Harvard 1953. Management succession in small a growing enterprises.

KEITH DAVIS, Ph.D. Ohio State 1952. Channels of executive communication.

WILLIAM H. DAY, Ph.D. Ohio State 1953. The marketing of colorizer paint.

HORACE J. DEPODWIN, Ph.D. Columbia 1953. Corporate tax liabilities.

JAMES D. EDWARDS, Ph.D. Texas 1953. Some significant developments of public accou ing in the United States.

Isadore Fine, Ph.D. Columbia 1952. Retail trade area measurement techniques applied to Fort Atkinson, Baraboo and West Bend.

Edwin B. Flippo, Ph.D. Ohio State 1953. An analysis of methods used to maintain and sustain employee profit sharing plans in selected companies.

Roland W. Funk, Ph.D. Chicago 1951. Theoretical foundations for inventory accounting.

Fredric H. Glade, Ph.D. New York 1952. An examination of the economic and social functions of the advertising agency.

Oscar R. Goodman, Ph.D. Wisconsin 1953. Forecasting methods used in sales planning.

Lester Greene, Ph.D. New York 1953. Financial aspects of inventory valuation methods.

Charles H. Griffin, Ph.D. Texas 1953. Petroleum refinery accounting.

James H. Healey, Ph.D. Pennsylvania 1953. An analysis of the span of control and selected coordinating and control media employed by chief executives of Ohio manufacturing companies.

Cyril C. Herrmann, D.C.S. Harvard 1953. Problems of new businesses developing new products.

Robert G. James, Ph.D. Harvard 1953. The effect of inflation on the determination of depreciation.

Charles E. Marberry, Ph.D. Illinois 1952. Income administration policies of industrial corporations.

Martin V. Marshall, D.C.S. Harvard 1953. The problems and limitations of vending.

Stuart W. McFarland, Ph.D. Pittsburgh 1952. The marketing operations of industrial distributors, with particular reference to the Cleveland, Ohio, area.

Ishmael E. McNeill, Ph.D. Texas 1953. Accounting for the finding, production, and processing of natural gas.

Robert Myers, D.C.S. Indiana 1952. Contests and awards for motivation of salesmen.

Carter C. Osterbind, Ph.D. American 1953. An appraisal of the usefulness of partial equilibrium theory in marketing research and analysis.

James M. Owen, Ph.D. Louisiana State 1953. An analysis of the traditional accounting treatment of deferred charges.

Gerald F. Price, Ph.D. Pittsburgh 1953. Retail store mortality in Denver, Colorado.

Karl H. Rahdert, D.C.S. Indiana 1952. Criteria for raw materials inventory control.

Melvin E. Salveson, Ph.D. Chicago 1952. On a rational and quantitative method of production planning and scheduling.

Marvin Tummins, Ph.D. Louisiana State 1953. The use of the Poisson distribution by the auditor.

Paul A. Vatter, Ph.D. Pennsylvania 1953. Structure of retail trade by size of store—an analysis of 1948 census data.

Elmer R. Young, Ph.D. Columbia 1953. Some important distribution cost accounting theories and practices.

VACANCIES AND APPLICATIONS

The Association is glad to render service to applicants who wish to make known their availability for positions in the field of economics and to administrative officers of colleges and universities and to others who are seeking to fill vacancies.

The officers of the Association take no responsibility for making a selection among the applicants or following up the results. The Secretary's Office will merely afford a central point for clearing inquiries; and the *Review* will publish in this section brief description of vacancies announced and of applications submitted (with necessary editorial changes). Since the Association has no other way of knowing whether or not this section is performing a real service, the Secretary would appreciate receiving notification of appointments made as a result of these announcements. It is optional with those submitting such announcements to publish name and address or to use a key number. Deadlines for the four issues of the *Review* are February 1, May 1, August 1, and November 1.

Communications should be addressed to: The Secretary, American Economic Association, Northwestern University, Evanston, Illinois.

Vacancies

Research in economic security: National organization located in Chicago seeks person with wide research background and knowledge of survey work, preferably with some experience in conducting meetings and educational programs. P158

Economic analyst: Well-known national organization doing long-range economic study work on national business problems desires trained research economist with writing ability. Location, Chicago. Give personal qualifications, including education, job experience, and salary record. Replies will be held in strict confidence. P159

Security analyst and portfolio manager: Investment counsel company with head office in New York City wishes a man or woman with an economics background and an interest in securities to train for permanent position as security analyst and portfolio manager. P160

Economists: The TVA Fuels Economics Section of the Division of Power Supply is accepting applications for certain positions. This Section is responsible for forecasting fuel requirements (principally coal), analyzing costs of fuel and forecasting changes in such costs, recommending size and timing of invitations for bids, nature and term of contracts, provisions for cancellation, escalation, etc., and analyzing comparative coal transportation costs. Salaries range from $3,875 to $7,500 per annum, depending upon academic training and actual experience. Write to W. Sherrill Milliken, TVA, Chattanooga Personnel Office, Chattanooga, Tennessee.

Economist—Chicago area: Suitable training and experience to testify as an expert witness on value in condemnation proceedings of two-flat building. Retainer, $40.00 a day. P161

Economists Available for Positions

Accounting, applied economics, business administration: Woman, Ph.D., C.P.A. Professor of business administration seeks university professorial or research appointment; extensive experience and publications. Would consider research post in foundation or company. Available in January, 1954. E109

Current business analysis, economic forecasting, business cycles, market research, national income and product analysis: Man, 36, married, M.A., Ph.D. requirements nearly completed. Ten years of experience in analysis of current economic developments and in forecasting; 5 years as economic analyst-writer on staff of nationally known business magazine; brief university teaching experience in current economic problems but qualified to teach business cycles, money and banking, fiscal policy and related fields. Desires research-analysis or teaching position. E224

Principles, value and distribution, history of thought, cycles, government and business, public utilities, systems, public finance, corporate finance: Man, 32, married, B.A., M.A., Toronto, Ph.D., Wisconsin. Teaching since 1946; broad occupational and background experience; veteran; fellowships; articles in preparation; active in Y.M.C.A. Available immediately. E332

AMERICAN ECONOMIC REVIEW

VOL. XLIII, NO. 4 PART 2 SEPTEMBER, 195

SUPPLEMENT

GRADUATE EDUCATION IN ECONOMICS

By HOWARD R. BOWEN

PRINTED BY GEORGE BANTA PUBLISHING COMPANY

Publication Office: 450 Ahnaip Street, Menasha, Wisconsin

Executive Office: American Economic Association, Northwestern University, Evanston, Illinois

The American Economic Review, including four quarterly numbers, the *Proceedings* of the annual meetings, the *Directory* and supplements, is published by the American Economic Association and is sent to all members five times a year, in March, May, June, September, and December.

Membership dues of the Association are \$6.00 a year, \$5.00 of each year's dues being in payment of a year's subscription. Subscriptions to the Review by non-members are \$6.00 a year. Single copies, \$1.50.

Correspondence relating to the *Papers and Proceedings,* the *Directory,* advertising, permission to quote, business matters, subscriptions and membership in the Association may be sent to James Washington Bell, Northwestern University, Evanston, Illinois.

Entered at the post office at Menasha, Wisconsin, as second class matter. Acceptance for mailing at special rate of postage provided for in the Act of February 28, 1925, embodied in paragraph 4 section 412 P. L. and R., under the provisions of Sec. 34-40 Par. (D). Authorized September 13, 1928. Printed in U.S.A.

Price, \$2.50

PREFACE

In the United States today several thousand persons of varied bac grounds and interests are serving in capacities in which they are ı ferred to as "economists." This number is steadily growing. Ind vidually, many economists are in positions of great influence. Colle tively, they occupy an important place in our society as formulators economic ideas, as interpreters of events, as consultants on public a private policy, as administrators, and as teachers.

In view of the increasing importance of economists in Americ society, it is appropriate that the recognized professional associati in this field, the American Economic Association, should sponsor study of the economic profession—a study to provide information the activities of economists and on the recruitment and training future members of the profession.

This study was conceived as an outgrowth of an earlier investigati conducted by a committee of the Association under the general cha manship of Professor Horace Taylor of Columbia University. T earlier study, which was confined to education in economics at t undergraduate level, resulted in a report, "The Teaching of Unde graduate Economics," *American Economic Review* (Supplement), D cember, 1950. As this report was nearing completion, the Executi Committee of the Association appointed an *ad hoc* committee to co sider the feasibility of a study of education in economics at the gradua level. The members of this group were G. L. Bach of the Carneg Institute of Technology, Milton Friedman of the University of C cago, I. L. Sharfman of the University of Michigan, and J. J. Sper ler of Duke University. D. Gale Johnson of the University of C cago served for a time during the absence of Prof. Friedman. This *hoc* committee reported favorably on the project. The Executive co mittee then submitted a proposal to the Rockefeller Foundation fo grant to finance the study. The grant was approved and the prese study was undertaken during the academic year 1951-52.

Under the agreed plan, the Association has served as sponsor a publisher of the study, but has not attempted to give official sancti to the report or to the recommendations contained therein. The stu has been carried on under my direction and I am solely responsible the conclusions and recommendations.

This is a document based upon observations and facts selected a interpreted by one person who spent the greater part of a year thinki

about the subject, collecting data, and talking with interested people. It is in no sense a report of a committee or of any broadly representative group of economists. However, in the preparation of the report, I consulted widely and was influenced by the opinions, judgments, and criticisms of many persons—especially the members of the *ad hoc* committee.

The objectives of the study have been to describe the role of economists in American life, to survey present practices in the recruitment and training of economists, to clarify the objectives of graduate education in economics, to consider standards, and to offer recommendations toward improving graduate training and increasing the usefulness of the profession. These ambitious objectives have not, of course, been fully achieved. I hope, however, that a useful beginning has been made and that the study will stimulate further and continuing discussion of the many issues considered and recommendations offered.

In general, the recommendations are of a modest sort—looking toward gradual evolution rather than sweeping reform. My observation of present practices and trends in the education of economists has led to the view that on the whole a good job is being done, and that revolutionary changes would not be desirable even if they were possible. Present conditions in the education of economists bear little resemblance to those in medical education as reported by Abraham Flexner in his famous and influential report of 1910.[1]

I found no examples of shoddy graduate education in economics and I can make no "shocking" revelations. On the other hand, I found no examples of smug complacency among graduate faculties of economics. I was impressed by the prevailing spirit of critical self-examination and of earnest endeavor to strengthen educational programs.

There are, of course, substantial differences among the various graduate departments of economics not only in their practices, but even in their objectives. In view of such differences, there was always the temptation to suggest that all departments should conform to one's own conception of the ideal. I have resisted this temptation because it has seemed to me that up to a point there is great virtue in diversity and in division of labor, and that to advocate uniformity would be both unwise and fruitless. Therefore, I have not attempted to lay down rigid standards or to define the content of a "good" educational program in great detail. But I have tried to face the question of what knowledge and abilities economists should have in common, and thus to consider what is the irreducible minimum in the program of edu-

[1] *Medical Education in the United States and Canada,* A report to the Carnegie Foundation for the Advancement of Teaching, Bulletin No. 4, New York, 1910.

cation for persons who are to be entitled to call themselves "econc mists." Moreover, my recommendations are intended as genere suggestions to be applicable in different degrees and in different way to different departments. My feeling is that each department mus interpret these recommendations in the light of its own role, its ow objectives, and its own unique history.

In defining the scope of economics for purposes of this study, I hav not attempted to differentiate sharply between "economics" and th several sub-fields which have splintered off from it and the severa disciplines which at some point are tangential to it. I have leane toward a broader rather than narrower definition of the field, and hav considered explicitly the relationships among the various sub-fields an related disciplines.

Similarly, I have not attempted to distinguish sharply betwee those matters which are common to all fields of graduate education an those which are peculiar to economics. I have avoided this partly be cause I was unable to make the distinction clearly and partly because thought it useful to consider the rules, procedures and standards o graduate schools as applied specifically to the field of economics.

The study is based largely upon three sources: (1) published litera ture, (2) questionnaires, and (3) personal interviews. I should add tha some of my own experience as student, teacher, and administrator ha doubtless found its way into the report.

The published literature in the field is not large. Useful studies an reports on graduate education have been issued by the America Council on Education, U. S. Office of Education, Association of Ameri can Universities, Social Science Research Council, and other agencie Several professional societies, notably the American Chemical So ciety and the American Political Science Association, have issue reports based on studies made by their committees. And a considerabl volume of research on the demand for and supply of trained professiona talent has been in progress at the National Research Council, America Council of Learned Societies, and the Commission on Human Re sources and Advanced Training.

Separate questionnaires were sent to the following classes of re spondents: chairmen of graduate departments of economics; pro fessors of economics; graduate students who received advanced degree in economics in 1939-40 and 1949-50; graduate students in residenc in 1952-53; and employers of economists in colleges, government, an business. Titles and brief descriptions of the questionnaires and th number mailed and returned are shown in the appendix. In the text whenever data derived from the questionnaires are presented, th source is cited by reference to the schedule number and the number o

respondents. The nature of the source can then be ascertained by consulting the Appendix.

Since the object of the questionnaires was primarily to obtain opinions and judgments from a broad range of institutions and individuals rather than to obtain precise quantitative estimates, no attempt was made to utilize refined sampling procedures or to adjust the results for non-response. The returns from each questionnaire, however, were widely dispersed with respect to geographic area, type of institution, and specialty of respondent. Moreover, the subjects included in the questionnaires were also frequently covered in personal interviews. I believe, therefore, that a reliable record of the range and variety of opinion and practice has been obtained—even though a precise estimate of the prevalence of any given opinion or practice is not always possible. Some of the questionnaires were long and difficult. I am deeply indebted to the hundreds of economists who expressed their genuine interest in the study by filling out the questionnaires so informatively.

In the course of the study I conducted personal interviews with 250 professors, heads of departments, and graduate deans at 30 universities located in all parts of the country. I regret that I was unable to visit all of the institutions (perhaps 135) offering graduate work in economics. I did try to include a cross-sectional sample of the entire group of institutions and also to visit those having unique or unusual features in their graduate programs. At every institution which I was privileged to visit, faculty members and administrative officials gave unstintingly of their time and advice. I also conducted numerous interviews with government officials, graduate students, former graduate students, business economists, and others.

I regret that I can name only a few of the several hundred persons who contributed significantly to this study. I should like to acknowledge especially the assistance and advice offered by: Frank H. Knight, John H. Williams, Harold A. Innis, and Calvin B. Hoover, the four successive Presidents of the American Economic Association who served during the period of the study; the members of the executive committee of the Association; the members of the *ad hoc* advisory committee for the study; James Washington Bell, the efficient secretary of the Association; and Horace Taylor, chairman of the earlier study on undergraduate education in economics. The following persons offered many valuable suggestions or reviewed sections of the manuscript: F. M. Boddy, Lois S. Bowen, O. H. Brownlee, Malcolm M. Davisson, Dudley Dillard, James S. Earley, J. K. Galbraith, Claude E. Hawley, R. B. Heflebower, Walter E. Hoadley, G. V. Lannholm, Mary Lois Lucas, John Perry Miller, Paul A. Samuelson, Edward S. Shaw, Carl S. Shoup, Elbridge Sibley, J. F. Wellemeyer, Paul Webbink, Dael Wolfle, and

David McCord Wright. Invaluable assistance in the analysis of data and preparation of the manuscript was given by Natalie Horowitz Monroe Newman, and Mrs. W. J. Healey.

A special word of appreciation is due the Rockefeller Foundation for its generous financial support of the project and to Dr. Joseph H Willitts of that Foundation who was most helpful in the organization of the study.

Chapter 1

CONCLUSIONS AND RECOMMENDATIONS

In this chapter I shall try to draw together concisely the princip conclusions and recommendations emerging from the study. In sul sequent chapters, these are developed in detail, with supporting dat arguments, and qualifications. They are presented here to provide convenient summary of the entire study.

The Profession (Chapters 2 and 3). In the United States toda there are perhaps 13,000 persons serving as economists. This is a ver rough estimate because there are no well-established criteria for di tinguishing economists from others. With various conceivable criteri the number might be as low as 4,000 or as high as 20,000. The group persons called "economists" (regardless of how that term is defined are a heterogeneous group including persons of widely varied bacl grounds and interests. They are employed primarily in higher educa tion, government, and business. Employment in government has i creased greatly in recent decades. Employment in private busines though still small in the aggregate, is steadily increasing. Today, mar departments of economics in private corporations compare favorab —in staff and budgets—with many college and university department

The salaries of most economists are within the range of $3,000 $12,000. Limited data suggest that salaries are higher in business ar government than in higher education. However, when allowance made for the shorter work year of college teachers and for their oppo tunity to obtain outside compensation, it is not clear that the differen is marked.

The market for economists (at prevailing salaries) has for mar years been brisk. There is little evidence that economists have e countered serious placement difficulty. On the other hand, there is severe "shortage" of economists (at prevailing salary scales), such is reputed to exist for physical scientists and engineers.

In a recent study of the status of various occupations, as judged l a cross-sectional sample of the American public, economists stood w below *all* the other learned professions covered by the study.

Objectives and Standards in Graduate Education (Chapter 4). T profession is apparently in rather general agreement on objectives a standards for graduate education in economics. There is consideral uniformity in the *formal* standards and objectives operative at vario universities. Variations in standards are probably due as much differences in quality of students admitted as to any other factor.

From the point of view of students, the principal objective of graduate study in economics is to prepare for a career. For them it is professional education. Most students are looking to careers in education, government, and business in which technical knowledge of economics will be useful. These objectives correspond approximately to the actual employment of graduate students after completing their studies.

From the point of view of many graduate professors, the principal objective is to produce "scholars." This objective is not regarded, however, as inconsistent with the vocational objective of students. Most graduate professors and other economists feel that the best preparation for professional work in economics consists of education oriented toward scholarship. Even though employment opportunities of economists are expanding into new fields, their formal education should continue to place emphasis on fundamentals and on scholarship. Graduate departments of economics should resist any temptation to convert into trade schools. This means, among other things, that there should be a solid "common core" for all students who are to be awarded advanced degrees in economics—regardless of their specific career objectives. There can be diversity among universities and diversity in the programs of individual students at given universities; but this should not be at the expense of the basic nucleus of substance and technique which should bind the profession together and which should enable economists of all types and persuasions to communicate with one another.

Proposed specific standards for the Ph.D. and the master's degree are presented in summary form on pp. 42-52 and 60-62. There is no need to reproduce them here. The reader is urged to refer to these summaries because they represent the very heart of this report.

The master's degree has fallen into fairly low estate at many institutions and should be upgraded. Students may legitimately study educational methods or technical specialities within economics as preparation for specific vocations; but they should not receive the master's degree in *economics* without completing a basic and relatively non-specialized program involving substantial knowledge of the field, a thesis or its equivalent, and a level of professional competence as an economist. The master's degree (with a thesis) should be taken by most students who later go on to the doctorate.

Recruitment and Selection of Students (Chapters 5 and 6). In recent years, graduate departments of economics have drawn students whose average ability (as measured by tests and college grades) is about equal to the average of all graduate students. The average ability of economics students is lower than that of students in some of the physical sciences and higher than that of students in some of the

less "academic" fields such as fine arts, physical education, home economics, and social work. While current quantitative demands for economists probably do not justify the recruitment of larger numbers into the field, it would be desirable to recruit more students of high quality.

Students make their decisions to enter graduate study in economics relatively late. Only about a third of those in graduate study had decided before their senior years and only two-thirds had decided prior to graduation from college. Recruitment is primarily a function of the undergraduate colleges. Undergraduate departments of economics should help their students become aware of the fact that there is a profession of economics and that it offers wide and varied career opportunities. Students often have direct acquaintance with law, medicine, business, agriculture, and even with chemistry, physics, and engineering. But they are unlikely to know about economics as a profession unless conscious efforts are made to provide information on this subject. Special attention should be given to the counselling of superior students who have elected economics as an undergraduate major. Graduate departments should have more scholarships for *first-year* graduate students, and they should actively seek out superior talent.

Because of difficulties in predicting the success of individual students in graduate school, and because the pressure on enrollment is usually not great, most institutions will be well-advised to adopt a relatively lenient admissions policy combined with a rigorous and prompt weeding out of unsuitable students. Only at those few institutions at which demands for admission exceed reasonable capacity will a rigorous admissions policy be indicated.

Undergraduate offerings in economics vary widely from one institution to another. Moreover, one-third of all graduate students in economics majored in some other field as undergraduates. Therefore graduate students in economics have very uneven backgrounds. As a result there is a tendency in graduate departments to assume that students start their graduate careers with little useable knowledge of economics and with little common experience in other fields. This situation is unwholesome. Firm but gradual action should be taken to stiffen substantive admission requirements and prerequisites. The profession should work toward the formulation of minimal standards for the content of the undergraduate major and toward the requirements of the equivalent of this major for admission to graduate study in economics. An applicant should be prepared at the undergraduate level in at least principles of economics, elementary statistics, money and banking, intermediate economic theory, and in one or two other fields of economics. He should have a knowledge of mathematics through

calculus and a rudimentary knowledge of the major concepts of accountancy.

Greater use of tests is recommended in connection with admissions. Tests are useful (a) as a basis for deciding on the admission of particular students, (b) as a basis for counselling, identifying deficiencies, and later appraisal of the student, and (c) as a method of determining the quality of an institution's applicants in comparison with those of other institutions. The Aptitude Test and the Advanced Economics Test, both parts of the Graduate Record Examinations, are recommended for this purpose.

A rigorous selection policy after admission would involve: (a) the placing of weak students on probationary status, (b) a qualifying examination after admission, and (c) use of the master's degree as a major screening device. Present mortality rates are such that out of 100 students admitted to graduate standing about 40 fail to receive the master's degree or to complete successfully the first year of work. A more rigorous selection policy would increase this rate of mortality.

Content (Chapters 6 and 7). The proliferation of economics in recent decades and the introduction of many new techniques has placed increasing pressure on graduate students. They are asked to assimilate an enormous and varied amount of substance in a few graduate years; they become so completely preoccupied with technicalities that they have little time or energy to acquire the kind of historic, philosophical, and institutional breadth which would give them perspective and judgment.

A partial solution to the problem is to require of all students a well-balanced "common core" of studies designed to provide a solid base for further work in the field. A recommended common core for both the master's degree and Ph.D. is summarized in table 28 on p. 108. For the master's degree, this core includes theory and statistics; for the Ph.D., it includes, in addition, economic history, history of economic thought, and research methods. Beyond the common core, students should be required to achieve both breadth and specialization. Greater attention should be given to achieving a fruitful balance between theoretical and empirical studies.

Research Tools and Verbal Skills (Chapter 8). The important research tools for economists include foreign languages, mathematics, law, accountancy, socio-psychological techniques, historical techniques, and possibly others. No student can be expected to have a useful knowledge of all or many of these tools. A doctoral candidate should, however, achieve a genuine mastery of at least one of them. The particular tool selected should be relevant to his interests and objectives. Present foreign language requirements are on the whole unsatisfactory

for students of economics. While foreign languages are useful tools for economists they are not the only important ones. Students should have the options of choosing from among many tools; at the same time, whatever tool they select should be mastered.

All students should have a sufficient orientation in simple mathematical ideas, symbols, and mode of thought to make economic theory and statistics readily intelligible. In the long run this knowledge should be part of the admissions requirements. More advanced use of mathematics would be regarded as one of the research tools which the student might elect.

High standards of written and oral communication should be required. To develop these skills, students should be given many opportunities for speaking, discussing, and writing; and all master's candidates should prepare theses.

Training for Research and Teaching (Chapters 9 and 10). Competence in research is one of the major objectives of graduate study—regardless of the student's career plans. The first requirement for good research training is an environment in which students have frequent contact with an active research program. The graduate department of economics should emulate, in spirit and practice, the research environment of a scientific laboratory. Students should be drawn into research as observers and as participants. An organized research agency within the department may be a useful aid in creating a desirable kind of research environment. In the research program and in research training, a balance between empiricial and theoretical work should be maintained.

The master's thesis is an essential part of research training. Current tendencies to devalue or eliminate the thesis should be reversed. Professors should be given time to work more intimately with first-year students. Doctoral dissertations should be written mostly in residence and should be written in close consultation with one or more professors. The scope of the doctoral dissertation should be narrowed to that which can be completed at a high standard of quality.

Teaching ability is an asset to an economist regardless of his specific job. Almost all economists are required to impart knowledge to others —whether they are employed in higher education, government, or business. It is appropriate, therefore, that most students should develop some competence as teachers just as all should be expected to have some competence in research. This argues again for similar basic training for all students regardless of career objectives. Teacher training does not, however, require major alteration of the graduate program. It would be desirable to require or encourage students to gain more experience in oral presentation and discussion. Seminars in

college teaching would be useful. Teaching assistantships should be transformed into apprenticeships in which the student works under careful guidance and assistance, and progresses from less to more responsible functions. The efforts of the graduate department should be supplemented by in-service training on the part of institutions employing young teachers.

Time Span of Graduate Study (Chapter 11). The average time in residence between the bachelor's and master's degrees is 1.5 years, and between the bachelor's and the Ph.D., 3.7 years. The average elapsed time between the bachelor's and master's is nearly 3.5 years, and between the bachelor's and the Ph.D., 10 years.

The average period of *residence* is not a cause for concern. If anything, it is too short because too many students do substantial amounts of their work *in absentia*. The average elapsed time, on the other hand, is excessive. The long span of years is the result of inadequate preparation for graduate study, floundering in the choice of a career, inadequate finances, procrastination, and overly-ambitious dissertations. The situation could be improved by better and earlier recruitment, use of financial assistance to see fewer students through to the degree rather than more through only to the preliminary examination, encouragement of students to write dissertations in residence, and dissertation topics of a scope that can be finished in a year or two of intensive work. The dissertation should not be thought of as a final scholarly effort of heroic dimensions representing the most advanced work of which the student will ever be capable; rather it should be a first major effort which, it is hoped, will be succeeded by a long series of later research enterprises.

The Graduate Department of Economics (Chapter 12). There are important differences between undergraduate and true graduate work—differences in content, in objectives, and in spirit. Therefore, a department of economics which offers graduate work should allot a distinguishable and fairly definite amount of staff-time, courses, funds, and facilities to the graduate program. There should be an identifiable *graduate department of economics* with its own institutional personality and its own *esprit de corps*. The supervision of theses and dissertations should be regarded as part of the regular teaching load of staff members, 5 or 6 theses to be counted as the equivalent of one course. The staff should contain a sufficient number of well-known and distinguished scholars to give the department status in the eyes of the profession. The staff should have diversity with respect to special fields, theoretical vs. empirical interests, scientific vs. policy interests, and academic vs. practical experience. To achieve adequate diversity would require a *graduate* staff of no less than 6 or 8 persons. There are both educational

and financial advantages in a sizeable student body. The best environment for graduate study, other things equal, is one in which the number of students exceeds perhaps 40. Most institutions have too few students for most effective work.

In recent years, teaching and research in economics have been subject to radical administrative fragmentation. Many new institutes, bureaus, schools, etc., have been created in which economics is a major field of interest. This movement has been the result of a variety of powerful forces, among them, the proliferation of economics into numerous specialties, the need for interdisciplinary approaches to new scientific and practical problems, the influence of pressure groups, and the effort to attract new money. On the whole, the consequences of this fragmentation have been undesirable. It has led to uneven development of the field, it has impeded communication among various specialists, it has led to narrowed training, and it has sometimes led to unwholesome relations with interest groups. It is not expected that the clock can be turned back, and all of these new agencies restored to the economics department. But a fresh examination of the situation is called for, and further fragmentation should be entered into with great caution. Efforts should be made to coordinate the various units interested in economics and to facilitate communication among them.

How might existing departments be encouraged to improve, and unqualified departments encouraged to discontinue graduate work or not to enter it? Several possible answers were considered. Accreditation by an outside agency is one possibility. This was not recommended. Another more promising possibility is for each department to subject itself, at least once every five years, to examination by a visiting committee of qualified outside members of the profession. Such a committee should be appointed by an outside agency such as the American Economic Association. Its report should be confidential for the use of the department and the general administration of the university. The expenses of the visiting committee should be borne by the university.

Instructional Methods (Chapter 13). In most departments graduate teaching does not differ significantly from undergraduate teaching. This is due partly to the uneven undergraduate preparation of the students. The result is that students do not achieve the intellectual independence and maturity that should be a major purpose of graduate education. Improvement might come through stricter requirements, greater reliance or seminars, workshops, cases, and problems. In short, there should be more creative activity for students as distinct from passive reading and listening. More attention could be given to providing awards and other incentives for distinguished work. Examina-

tion procedures could be improved. One possibility in this connection would be the use of standardized national examinations as part of the basis on which students would be judged. Such examinations, while they should not be the sole basis of evaluating students, would have the advantage of enabling each institution to compare its students with those of other universities, and thus to achieve somewhat more objective standards. The American Economic Association might take leadership in developing such examination procedures.

Graduate Study in Economics: a National View (Chapter 14). About 135 institutions in the United States and Canada offer and sometimes give graduate work in economics. Of these, about 70 award both the master's degree and the Ph.D., and 65 give only the master's degree. In 1951-52, these institutions had a combined graduate enrollment of roughly 3,000 students. During recent years they have awarded about 800 master's degrees and 200 to 400 Ph.D.'s per year. A large part of the graduate work is concentrated in a few institutions. Ten institutions award 60 percent of the Ph.D.'s and ten award 43 percent of the master's degrees. Only 6 institutions awarded 10 or more Ph.D's per year during the post-war period, and only 10 institutions awarded more than 20 master's degrees in 1950-51. The great bulk of institutions in the graduate field are awarding advanced degrees to only a handful of students.

Graduate departments of economics show little tendency to cooperate or to specialize. Each runs a relatively independent "show" and each tries to cover a broad range of specialties.

It is possible that special facilities in Washington and New York for the training of economists would be useful to supplement the facilities offered by universities. The Brookings Institution and the National Bureau of Economic Research might provide these facilities.

There are possibilities of improving the "adult education" of economists. For example, sabbatical leaves should be available for all economists, including those employed in colleges, business, and government; a few leading universities might provide short courses or extended conferences intended primarily for college teachers of economics; the American Economic Association might supplement the annual meeting with smaller and more extended conferences on specialized subjects.

Chapter 2

THE PROFESSION

The several thousand persons who are serving professionally as economists in the United States today are a heterogeneous group whose common distinguishing characteristics are by no means obvious. They have had widely varied education ranging from no formal study in economics to post-doctoral study in the field. They serve different classes of employers, among them, governmental agencies, educational institutions, research organizations, private business firms, and labor unions. A few are self-employed as private consultants or free-lance writers and lecturers. They perform a variety of functions: teaching, research, consulting, administration, writing, and lecturing. Often several of these functions are combined in a single person, and frequently individuals shift from one to another of these functions at various points in their careers, "success" often leading to administrative functions. Their professional interests cover a wide range of subject matter. Economists can be found whose interests border on history, ethics, or social psychology; others are interested in topics verging on statistical method or pure mathematics. Some are interested in the collection and interpretation of data; others confine themselves largely to theoretical studies. Some are concerned with detailed analyses of particular industries; others develop comprehensive theories of general equilibrium or sweeping studies of world economic development. Economists also differ in their views of their professional functions, in their conception of the scope and method of economics, and in the basic premises upon which they build their theoretical conclusions and their policy recommendations.

In a group so heterogeneous, one may easily question whether characteristics can be found to identify economists or to distinguish them from other professional groups. Apparently, the one common element is that all have (or profess to have) interest in and knowledge of some aspect of "that part of individual and social action which is most closely connected with the attainment and with the use of the material requisites of wellbeing."[1]

[1] Alfred Marshall, *Principles of Economics*, 8 ed., London, 1920, p. 1. Marshall's famous definition is apparently unsurpassed as a description of the field of interest of those who are called "economists." Compare "The Profession of Economist," in *The 1948 Directory of the American Economic Association, American Economic Review* (supplement), Jan. 1949, pp. 341-3.

As would be expected in so diverse a group, economists have not developed a tight professional organization which attempts to define criteria for admission or to regulate the professional activities of its members. The American Economic Association and other organizations in the field have virtually no requirements for membership beyond perfunctory endorsement of the individual applicant by one or more members. No licenses or examinations are required for setting oneself up as an "economist." All one needs is to find a job—or a clientele. This is often done with a minimum of formal education in economics. Many economists—especially in business, government, or free-lance activities—have acquired their professional knowledge and skills through individual study or through serving a kind of apprenticeship to more experienced persons.

TABLE 1.—EMPLOYMENT OF PERSONS WITH ADVANCED DEGREES IN ECONOMICS

	Total	Higher education	Other education	Public agencies	Private agencies			Unknown
					Total	Economic work	Other work	
Employment in 1940 of 845 persons who received the Ph.D., 1930–40[a]	100%	61%	1%	23%	8%	—	—	7%[d]
Employment in 1952 of 45 persons who received the Ph.D., 1939–40[b]	100	67	—	22	11	7	4	—
Employment in 1952 of 119 persons who received the Ph.D., 1949–50[b]	100	71	2	18	7	5	2	2
Employment in 1950 of 106 persons who received the Ph.D., from Columbia, 1931–50[c]	100	59	—	18	23	17	6	—
Employment in 1950 of 75 persons who passed orals at Columbia, 1931–50[c]	100	53	—	21	26	23	3	—
Employment in 1950 of 196 persons who received master's degrees from Columbia, 1931–50[c]	100	29	—	24	47	26	21	—
Employment in 1952 of 54 persons who received master's degrees, 1939–40 and 1949–50[b]	100	25	4	20	38	7	31	13

[a] E. V. Hollis, *Toward Improving Ph.D. Programs*, American Council on Education, Washington, 1945, pp. 86–7. Includes degrees conferred by 48 institutions.
[b] Data from Schedule X.
[c] J. W. Angell, *Occupations and Salaries of Former Graduate Students in Economics at Columbia University* (mimeographed), June 20, 1951.
[d] Includes 2% not gainfully employed.

Employment and Functions of Economists

Table 1 presents a compilation of data from several sources indicating the employment of persons who hold advanced degrees in economics. Although the data from the several sources are not entirely consistent, they indicate that roughly two-thirds of the Ph.D.'s and one-fourth of the masters are employed in higher education and that one-fifth to one-fourth of both groups are in public agencies.

Table 2 indicates the distribution of employment and of duties in 1940 of 845 persons who received the Ph.D. in economics in the decade 1930-31 to 1939-40, and of 22,509 persons who received the Ph.D. in all fields during the same period. Table 2 indicates that the percentage of Ph.D. economists in higher education is about the same as that for all fields combined; that relatively more economists are found in public agencies and fewer in private agencies; that the duties of economists lie largely in teaching, research, and administration; and that these duties are distributed in much the same way as those of the whole population of Ph.D's.

TABLE 2.—EMPLOYMENT AND DUTIES IN 1940 OF PERSONS WHO RECEIVED THE PH.D., 1930–31 TO 1939–40[a]

	Economics	All fields combined
Employment:		
Higher education, total	61%	60%
Universities	28	23
Colleges	28	32
University and college	4	3
Junior College	1	2
Other education	1	6
Public agencies	23	8
Private agencies	8	18
Employment status unknown	5	4
Not gainfully employed	2	4
Total	100	100
Duties:		
Teaching	48	47

Academic Economists

The traditional home base of economists has been the college or university. Economists who are attached to institutions of higher education commonly engage in a variety of activities. Their undergraduate teaching and textbook writing is an important part of liberal education, citizenship training, and training for business. Their graduate teaching helps to produce a flow of newly-trained economists for whom there is apparently a steady and insistent demand. Many of them engage in writing, public speaking, "extension" courses, and other adult educational activities in which they help to create broader understanding of economic affairs. Through their research work, they are an important source of data concerning economic life and they are a major source of theories, ideas, and proposals relating directly or indirectly to public policy. Finally, many of them are in demand by government and private organizations as part time consultants on specific questions of policy or administration.

According to a recent compilation, 4,003 persons are engaged exclusively in teaching economics in universities and colleges of the United States, another 1,085 persons are teaching economics and other social sciences and 887 are teaching the social sciences "in general."[2] These figures suggest that perhaps 4,000 to 6,000 economists—the precise number depending on one's definitions—are employed in institutions of higher education.

Graduate work in economics is generally regarded as an essential part of the training of academic economists, and the Ph.D. is often considered necessary either at the time an economist begins his academic work or within a few years. In one of the questionnaires, academic employers of economists (chairmen of departments of economics in institutions *not* giving graduate work in economics) were queried about the essentiality of the Ph.D. for prospective college teachers of economics. They responded as follows:[3]

	Per cent
Essential or highly desirable	55
Not essential *per se,* but necessary as a union card	19
Desirable but not essential	15
Not essential	6
Depends	2
No answer	3
Total	100

[2] James Washington Bell, "Report of the Secretary," *American Economic Review* (supplement), May 1951, p. 769.

[3] Schedule XI: 89 respondents.

It is clear that the great majority of these academic employers look with favor upon the Ph.D., although only a little more than half were willing to say that the Ph.D. is "essential or highly desirable." Most of those who were dubious about the Ph.D. questioned not the amount of graduate training but rather the suitability of the regimen leading to the Ph.D. for the training of college teachers.

Government Economists

The presence of economists in government is a relatively new phenomenon. As late as 1896, no persons were listed in the Federal Civil Service as "economists" and only 87 persons as statisticians. The word "economic" appeared in the Civil Service list for that year only with reference to an "economic ornithologist."[4] By 1931 there were about 600 persons classified as economists.[5]

A study published in 1941 reported 5,050 economists in the Federal government as of December 31, 1938 of whom 1,950 were agricultural economists.[6]

All of the above figures are estimates, and there are no precise data on the number of economists in the Federal government today. Figures indicating generally the numbers in executive agencies of the government are presented in table 3. The table probably does not include all civil service classifications in which some economists are to be found, but includes most of those in which there are significant numbers of economists. Economists are also employed in small numbers in the legislative branch of the federal government, in professional capacities within the armed services, and in state and local governments. Altogether, there are probably between 4,000 and 8,000 economists employed in governmental service.

The duties of economists in government as stated in a memorandum prepared by the Civil Service Commission are "to advise on; administer, or perform professional and scientific work in economics including the investigation, study, analysis, and interpretation of economic factors and conditions; advisory, consultative, or promotional activities related to economic problems; or the formulation, negotiation, and execution of economic policy."[7] The same memorandum distinguishes positions as *economists* from "those requiring a knowledge of particular industries or commodities, but not requiring a knowledge of the basic

TABLE 3.—ECONOMISTS IN EXECUTIVE AGENCIES OF THE FEDERAL GOVERNMENT, JUNE 30, 1951[a]

	Number
Professional classifications in which all incumbents are presumably economists:	
general economics	208
business economics	1,219
international trade and development economics	392
fiscal and financial economics	217
transportation economics	134
labor economics	462
agricultural economics	588
forest economics	41
Total	3,261
Professional classifications in which an unspecified portion of incumbents are economists:	
social science	473
foreign affairs	1,136
international relations	210
intelligence research	336
military intelligence research	894
statistics	2,038
Total	5,087
Non-professional classifications in which an unspecified portion of incumbents are economists:	
business analyst	2,450
agricultural marketing specialist	578
industrial specialist	4,009
commodity-industry analyst	1,655
Total	8,692

[a] Data on professional occupations from: U. S. Civil Service Commission, "Full-time Employees of Federal Executive Agencies in Professional Occupations," mimeographed release, 1952; other data supplied by Mr. Calvin P. Deal of the Commission.

principles and theories of economics or the ability to analyze a variety of economic interrelationships and to forecast the potential effects of developments in these industries or commodities on the economy as a whole." The memorandum then states that the "economist is responsible for applying basic economic theory, relating the problems involved to a broad economic context, and interpreting specific developments in terms of their significance to the economy as a whole as well as to a particular industry." More specifically, government economists serve as compilers of basic economic data, as scholars engaged in the formulation of basic theories and ideas, as consultants on questions of policy and administration, and as responsible administrators of public agencies

and programs. Almost always, in connection with these tasks, they perform educational functions in their daily contacts with their non-professional colleagues.

The Federal Civil Service designates the following special fields: agricultural economics, business economics, fiscal and financial economics, forest economics, general economics, international trade and development economics, labor economics and transportation economics. In addition to these major classifications many other positions or sub-classifications, filled by persons designated as economists, are actually found in the Civil Service.[8] And many positions not designated for economists actually require professional competence in that field, and are filled by trained economists.

The minimum requirement for entry into the Federal Civil Service as an economist is "the kind of training in the basic principles and theories of economics which can be gained through a major in economics culminating in graduation from a recognized college or university, or training equivalent in type, scope, and thoroughness."[9] In short, it is a frequent practice to accept persons into the Civil Service as junior professional assistants in economics who have only a bachelor's degree in economics or its equivalent. Such persons are able, if competent, to rise to high grades in the Civil Service without formal graduate education. Advancement becomes possible on the basis of experience and demonstrated ability. Graduate study can be used to a limited extent as a substitute for experience, but graduate study is not a formal requirement for any professional position in economics, and economists without formal graduate training are to be found at all levels in the Federal Civil Service.

A majority of the 22 supervisors of economists in the Federal government who responded to my questionnaires favored graduate study in the preparation of Federal economists. But they were not unanimous in this and they differed considerably on the amount of graduate study which they thought useful. When asked whether the Ph.D. is essential for persons who are expecting to reach the higher positions as economists in the Federal government, their answers were:[10]

[8] Among them are: land economists, city planning economists, housing economists, mineral economists, reclamation economists, Federal works economists, rural population economists, urban population economists, natural resources economists, fisheries economists, fish and wildlife economists, power economists, public health economists, public utilities economists, air transport economists, price economists, and manpower economists.

[9] Unpublished draft of Civil Service Memorandum "Introduction to Economic Series," *op. cit.*

[10] Schedule XII: 22 respondents.

Yes	23%
Desirable but not essential	46
No	27
No answer	4
Total	100

But most of those who were negative or doubtful about the Ph.D. indicated that they favored at least some graduate study for most high-level government economists, and no respondent expressed opposition to graduate study.

The supervisors of economists were then asked whether formal *graduate* training in economics is essential for persons who are expecting to serve in the lower grades as economists for the Federal government. To this question, their answers were:

Yes	64%
Desirable but not essential	14
No	18
No answer	4
Total	100

Those answering "yes" indicated unanimously that at least one year of graduate study or a master's degree was desirable, and of those answering "no," a few thought that the bachelor's degree or the bachelor's plus some "special courses" or "some graduate work" would suffice.

The conclusion emerges that most of this group of supervisors of economists in the Federal government regard some graduate study in economics as desirable for Federal economists at all levels, but that only a minority (23 percent) state unqualifiedly that the Ph.D. is essential even for positions of the higher grades.[11]

In some quarters there have been questions about the adequacy of the formal graduate training of many economists in the Federal government. A Committee of the American Economic Association on Economists in the Public Service, of which Professor Morris A. Copeland was chairman, indicated in 1946 their concern with what they viewed as an "upward trend in the proportion of government economists with little or no graduate training in economics."[12] This group recommended that in the selection of economists of the grade P4 (G.S.11) and above, the requirements should be amended to include the following: "(a) The candidate should be required to establish that he has done a substantial

[11] This conclusion agrees with that reached by a sub-committee under the chairmanship of Professor Ben W. Lewis in 1950. See "The Teaching of Undergraduate Economics," *American Economic Review* (supplement), Dec. 1950, pp. 125-6.

[12] "Report of Committee on Economists in the Public Service," *American Economic Review* (supplement), March 1946, p. 913.

piece of competent, independent economic research, the results of which are set forth in a written report a copy of which is permanently on file with the Commission or in a library approved by the Commission for the purpose; (b) the candidate should be required to establish that he is professionally, competently conversant with the current status of work in two broad phases of economics other than the phase of economics with which his qualifying independent research is concerned."[13] This proposal which would require the Ph.D. or nearly its equivalent for economists of higher grades, would significantly stiffen the requirements and doubtless block the promotion of many persons who might otherwise reach the higher grades under present regulations.

The Copeland Committee recognized, however, that the Federal government now relies, and will doubtless continue to rely, to a large extent on economists who have received a major share of their training on the job and who have not had substantial graduate study. Therefore, they recommended improvement in the quality of the experience and training which these economists receive on the job or concurrently with their work. Although the committee did not specify all the devices by which this could be accomplished, it is easy to suggest several possibilities: attendance at courses in universities or at seminars and classes provided by employing agencies;[14] in-service training for specific jobs; rotation of jobs so that the individual acquires a broad experience;[15] and leaves of absence for study or for practical experience in business, labor unions; etc. Two additional suggestions (in which I strongly concur) have frequently been made. First, that government economists should occasionally have the opportunity to teach or to engage in pure research in close contact with university economists. Second, that government economists should be permitted refresher periods, free from routine duties, similar to the academic sabbatical leave.[16] In this connection, a great opportunity exists for leading universities to provide fellowships or temporary teaching appointments to career economists in the Federal government. The highly successful Niemann Fellowships for journalists at Harvard University suggests the possibilities.

Business Economists

One of the newer and more rapidly growing professional opportunities for economists is in business corporations. Although a few econo-

[13] *Ibid.*, p. 916.

[14] The graduate school of the U. S. Department of Agriculture is an outstanding example.

[15] The tendency of many economists in Washington to move about from one agency to another helps to produce this result, and may actually be advantageous to the service, on balance.

[16] *Ibid.*, p. 915-917. See also, L. M. Short, *Personnel Problems Affecting Social Scientists in the National Civil Service*, Social Science Research Council, April 1946, p. 25.

mists have been so employed for many years, the numbers have undoubtedly multiplied in the past two decades. I should guess, on the basis of various fragments of data, that there may be as many as 600 persons serving today as professional economists in American business firms.[17] Because little information has been published on the role of business economists, I shall discuss this subject in some detail.[18]

My questionnaires to the heads of economics departments in leading business concerns yielded replies from 49 firms including 27 industrial concerns, 13 banks and insurance companies, 4 public utilities, 1 department store, and 4 other companies. Of the 49 respondents 9 carried the title of vice-president or partner, 2 were called "assistant to" the chairman or president, 16 had the title of director of research or equivalent, 15 were labelled "economists," and the remaining 7 had miscellaneous titles. The number of persons employed in the economics departments of the reporting firms is shown in table 4. The number of professional economists varied from 1 to 15 with the median at 3, the total number of assistants varied from 1 to 37 with the median at 5, and the total employment from 1 to 50 with the median at 8. Evidently, the economics departments of many corporations are substantially equal, in number of employees, to the economics departments of many colleges and universities.

The economics departments of the reporting companies were found to be highly placed in the corporate hierarchies. Of the 41 departments giving information on this subject, about half reported directly to the president or chairman, and half reported to a vice-president or controller.

The reporting business economists indicated that they (or their departments) are ordinarily concerned with a wide range of subjects. The subjects mentioned most frequently were general domestic business conditions, markets and prices of the firm's products, governmental policies, problems relating to money and capital markets, economic conditions in foreign countries, and capital budgets.

The work of the business economics departments is actuated by a

[17] The average number of economists in the firms reporting for this study was 4 (see table 4). If as many as 150 companies should have economics departments of the size of those in the sample, as seems likely, the number 600 would be a reasonable minimum. If many persons in market research activities were to be classd as economists, this number would be considerably higher.

[18] For other discussions of the functions and role of business economists, see: National Resources Planning Board, *Research—A National Resource*, Vol. III, "Business Research," Washington, June 1941; Francis C. Jones, "The Role of an Economist in Private Industry," *Michigan Business Review*, March 1950, pp. 6-9; Committee on Economic Policy, U. S. Chamber of Commerce, *Business Management and Economic Analysis*, Washington, 1947; *Business Week*, Jan. 10, 1953, pp. 134-46.

[a] Schedule VIII: 49 respondents.
[b] The term "professional economist" refers to "persons doing work for which a knowledge of economics at the professional level is a principal requirement."
[c] The term "assistant" is defined to include "assistants, clerks, interviewers, stenographers, etc."

wide range of objectives. Virtually all of the respondents consider that one of their main purposes is to provide information and judgments relative to specific managerial policies and decisions. And nearly all of them reported that they felt that important managerial decisions are sometimes influenced by the studies, analyses, and recommendations of the economic staff. But almost all of them also reported that they had other objectives—the most important being education of company officials and the business community on economic and public affairs. Of 36 respondents, 32 indicated that they felt that the work of the economic staff helps management to understand the broad economic and social implications of its decisions, and that management is thereby assisted in discharging its public responsibilities. A substantial number considered that their functions also include educational tasks associated with public relations and with the influencing of public policy.

In communicating the results of their studies and investigations, the economics departments of business firms utilize a variety of techniques. The more frequent and more important methods are the preparation of memoranda and publications for distribution within the company and conferences with company officials. Many of them, however, communicate with outside groups by means of publications and addresses, and with public officials through the briefs and testimony they help to prepare and through personal conferences.

In education and experience, the 49 responding business economists are a varied group. On the basis of their personal histories it would be difficult to generalize regarding the kind of education that is suitable for business economists or that prepares for this type of work. In education they ranged from no college work whatever, or college work in a field outside economics, to the Ph.D. in economics. Only a little more than half had taken any graduate work in economics or business administration. Only a fifth had received the Ph.D. in economics—though 3 more held the Ph.D. in mathematics of sociology. More than a third gave no indication that they had had any formal training, either at the undergraduate or graduate level, with economics as a major, though some of these may have studied economics as a minor field.

The relative lack of formal graduate education was apparently offset by a wide and diversified experience. All but a handful indicated that they had had experience in college teaching, government, or business operations, and 57 percent indicated experience in two or more of these activities. Yet only a few of the respondents indicated that they had had experience *with their present companies* in jobs other than research. Evidently, then, most business economists have been recruited from outside their companies after they have had a fairly wide experience in college teaching, government, or business. Apparently, formal academic training in economics has not been a major factor in the selection of these persons.

More light on the academic preparation of business economists is provided by data on the educational backgrounds of the professional economists employed as subordinate staff members in the economics departments of reporting companies. Almost all of the subordinate staff members have had some academic work in economics, and more than three-quarters of them have had some graduate work in economics. That the subordinate staff members as a group have had relatively more *academic* training in economics than the heads of the economic departments is at first surprising. It is to be explained, I think, by several factors: (a) senior business economists are on the whole older than the subordinate staff members and received their formal education when graduate work was less common than today; (b) they were recruited for their all-around judgment and their ability to work with top management rather than for their technical training in economics; (c) positions in business have until recent years been regarded with some suspicion by academic economists; and (d) graduate study does not carry the same prestige in business circles as in the academic world. Most of the subordinate staff members, on the other hand, have been recruited in recent years when a large supply of academically trained economists has been available. This supply has been the obvious source of talent for staffing the growing economics departments of the large

companies, particularly as it has been recognized that the techniques and judgments of the academically trained economist can be put to effective use in business management. It seems likely that more of the top business economists of the future will have had substantial academic training.

Another indication of the attitudes in business toward the training of economists comes from the responses of business economists on the question of whether the Ph.D. is essential for persons who are expecting to enter careers as economists in business and who hope to reach top positions.

The answers were:[19]

Yes	33%
Desirable but not essential	18
Doubtful	4
No	31
No answer	14
Total	100

However, almost all of those who were negative or doubtful regarding the Ph.D. thought that some graduate work in economics is essential. A third of this group considered the master's degree to be sufficient and the remainder felt that only some specialized graduate work in particular areas is needed. When asked their opinion as to whether formal graduate training in economics is "essential or highly desirable" for *subordinate* members of economics staffs in business firms, nearly all expressed judgments favorable to graduate study though only one respondent felt that subordinate professional staff members should have the Ph.D.

The conclusions from the data and judgments regarding graduate education of business economists are: (1) that the majority of top business economists have not had very much formal graduate training in economics, but that most of them favor substantial graduate training for their successors; (2) that a majority of subordinate professional economists in business have had considerable graduate work in economics and most of their superiors believe that they should have at least a year or two of graduate study.

Just as business enterprises have been developing economics departments in recent decades so labor unions have been organizing research and educational divisions employing substantial numbers of economists. Not only the American Federation of Labor, the Congress of Industrial Organizations, and other major labor organizations have developed research and educational staffs with professional economists but also many of their affiliates and independent unions have also found places

[19] Schedule VIII: 49 respondents.

for professional economists. A recent study reveals that research departments are found in 51 of 107 A.F. of L. affiliates, and in 28 of 69 independent unions.[20] In most of these, the research departments are separate from education departments, though in some the two functions are combined. The number of professional research personnel varies from 1 to 20 or more in these unions.[21]

Another growing employment for economists is in private consulting firms which serve a clientele consisting chiefly of business, labor unions, and foreign governments. Consulting economists on the whole perform functions similar to those of economists who are actually in the employ of these organizations.

The combined number of economists in business, labor, and private consulting firms may be somewhere between 1,000 and 1,500. This is, however, no more than a very rough guess.

Note on the Number of Economists in the United States

The question is frequently asked: How many economists are there in the United States? The answer depends, of course, on how one defines "economist." For example, one might define it in terms of formal education, and thus include only those who hold the Ph.D. in economics, or perhaps those who hold at least a master's degree in the field. Or one might define it in terms of functions performed, and thus attempt to count the persons qualified to hold jobs in which the work of an "economist" is performed. Or one might define it in terms of the titles assigned to persons or positions, and thus include anyone who is called an "economist." I have felt that in a profession as indefinite and as loosely-organized as economics, no purpose would be served by formulating an arbitrary definition of "economist," and then attempting to estimate the number of persons who would fit this definition. I have, however, collected a few fragmentary figures which indicate the approximate orders of magnitude.

In the preceding sections of this chapter, I have made very rough estimates of the number of economists in the three principal types of employment as follows:

	Minimum	*Maximum*
College and university	4,000	6,000
Government	4,000	8,000
Business and other	1,000	1,500
Total	9,000	15,500

[20] J. B. S. Hardman and M. F. Neufeld, *The House of Labor: Internal Operations of American Unions*, New York, 1951, p. 230.

[21] *Ibid.*, p. 230. For a discussion of the educational and communications activities of unions, see pp. 171-225 and 419-82.

In 1952, there were 7,267 members of the American Economic Association.[22] This figure doubtless includes persons who would not be regarded as economists under any reasonable criteria and certainly fails to include persons who would unquestionably qualify as economists. For example, a check of the records of the Association revealed that only 71 of 141 individuals who received the Ph.D. in 1939-40, and 159 of 391 who received the Ph.D. in 1949-50 were members of the Association in 1952. And among economists who do not hold the Ph.D., the proportion of non-membership is probably relatively higher. I would judge, therefore, that the membership of the Association grossly understates the number of economists in this country.

Another figure comes from the registration of economists by the National Roster of Scientific and Specialized Personnel. This organization reported the following numbers of registrants as of December 31, 1945:[23]

with the Ph.D.	1,642
with master's degrees	1,923
with bachelor's degrees	3,133
without degrees	651
Total	7,349

These figures almost certainly understate the number of economists. For example, there were almost surely more living persons holding the Ph.D. in economics in 1945[24] than the 1,642 who were registered. The registration of persons with master's degrees was probably even less complete.

Another approach to the problem of deriving the approximate number of economists is (1) to estimate the number of living persons who have been awarded advanced degrees in economics and (2) to estimate the number of these persons who are serving in capacities for which professional knowledge of the field is essential. During the period from 1910 to 1952, American universities awarded about 4,900 Ph.D.'s and about 19,000 master's degrees in economics. (The figure for the Ph.D.'s is fairly reliable but for the master's degrees very rough.) Most of those who received the doctorate during this period also received master's degrees. Therefore, to avoid double-counting and to obtain the number of those for whom the master's was the highest degree, the total number of master's degrees should be reduced by

[22] American Economic Association, *Information Booklet,* 1953, p. 14.

[23] James Washington Bell, "Report of the Secretary," *American Economic Review* (supplement), May 1951, p. 769.

[24] About 3100 Ph.D's in economics were awarded between 1910 and 1945. Allowing for mortality, emigration, immigration, etc., it seems probable that the number of Ph.D.'s living in the United States was not less than 2,500 in 1945.

4,900. This leaves about 14,000 persons who received master's degrees during the period but who did not receive doctorates.

During the period from 1910 some mortality has occurred; however, it has probably been small because the great bulk of the degrees were awarded within the past 30 years, and more than half since 1940. Assuming a mortality of one-fifth, this would leave about 4,000 surviving Ph.D.'s and 11,000 surviving masters.

Some of the recipients of degrees were foreign citizens and now live abroad; others may have emigrated to other countries. On the other hand some individuals with degrees in economics from foreign universities have migrated to this country. The net effect of this migration is unknown; I have assumed that the two movements have been counterbalancing.

These calculations would suggest that there are about 15,000 living persons in the United States who hold advanced degrees in economics. Some holders of advanced degrees, however, do not pursue economics as a profession. Therefore, if we count as economists only those who have advanced degrees and who follow the profession, another reduction in the number is necessary. Table 1 (p. 10) indicates that the great majority, perhaps 95 percent, of Ph.D.'s are employed in higher education, in public agencies, and in economic work within private agencies. These are the types of employment in which they are likely to be serving as professional economists. I have assumed, then, that about 95 percent of the living holders of the Ph.D. in economics are professional "economists." These are estimated, then, at 3,800 (95 percent of 4,000).

Similar data for those with master's degrees (table 1) indicate that from two-thirds to four-fifths are employed in higher education, public agencies, and economic work within private agencies. On the other hand, almost all of those who passed the oral examinations but did not complete the Ph.D. were engaged in professional work. It would seem reasonable to assume then, that perhaps four-fifths of all the persons who hold the master's degree but not the Ph.D. are engaged in professional work. This would mean that of the estimated 11,000 holders of the master's degree in economics, about 8,800 could be classed as "economists." Adding these to the Ph.D. group, gives a total of 12,600 persons with advanced degrees in economics who are serving in professional capacities. To these should be added an unknown but substantial number of persons serving as professional economists who have no advanced degrees in economics. One might guess, on the basis of these calculations, that there are more than 13,000 persons serving as economists in the United States.

The net conclusion of my investigation of the number of economists

in the United States is that, in the absence of definite criteria for distinguishing economists from others, it is impossible to set any one precise figure. At one extreme, if the term "economist" is restricted to persons holding the Ph.D. and pursuing the profession, the number would be about 4,000. At the other extreme, if one included every person who is doing work requiring some knowledge of economics, regardless of his formal education and regardless of the level of the work, the number might exceed 20,000. Between these two extremes, the number would depend upon the definition of "economist" in terms of educational level and nature of jobs performed. To date there is no authoritative or generally accepted definition of an economist which makes possible the designation of any particular number.

Chapter 3

CONDITIONS IN THE PROFESSION

This chapter is concerned with the salaries of economists, the market for their services, and the status of the profession.

Salaries of Economists

Because a large proportion of economists are employed in college teaching and in government service, their salaries are usually related to the somewhat conventional earnings in these two types of employment.

The pay scales of the Federal Government (as of 1952) provide that a college graduate who enters the Civil Service without experience as a Junior Professional Assistant will receive an annual salary of $3,410. A person with a master's degree in economics, and no experience, will probably receive $4,205 and one with a Ph.D. $5,060. (See table 5.) As a new appointee progresses he may ultimately reach one of the higher brackets. Many will reach the range from about $6,000 to $9,000, a few will pass the $10,000 mark, and a very few may enter the "super-grades" which pay from $12,000 to $14,800.

Available data on the salaries of college teachers indicate that they are probably somewhat lower than salaries in the Federal government. However, they are expressed in terms of the academic year of 9 or 10 months, and academic positions often provide perquisites and opportunity for supplementary earnings;[1] hence it is not certain that teaching pays less than government service for personnel of equal quality.

Table 6 presents data on the 1951-52 salaries of teachers in all fields in 40 leading colleges and universities. The salaries reported in this table are doubtless higher than the national averages because only leading institutions are included.

Another indication of the earnings of economists is provided by a study of the salaries in 1950 of persons who were graduate students in economics at Columbia University during the period 1931-1950. These data, presented in tables 7 and 8, were compiled by Professor J. W. Angell and kindly made available by him. These figures show several

[1] Professor George J. Stigler concludes: "In sum, more than 50 per cent must be added to the salaries of college teachers in making comparisons with earnings in independent professions. With this correction in 1941, the 'net advantages' of college teaching exceeded those of dentistry, and were almost equal to those of law and medicine." *Employment and Compensation in Education,* National Bureau of Economic Research, Occasional Paper 35, New York, 1950, pp. 62-3.

TABLE 5.—PAY SCALES FOR PROFESSIONAL WORKERS IN THE FEDERAL GOVERNMENT, 1952[a]

Grade		Salary range
Professional	"General service" equivalent	
1	5	3,410– 4,160
2	7	4,205– 4,955
3	9	5,060– 5,810
4	11	5,940– 6,940
5	12	7,040– 8,040
6	13	8,360– 9,360
7	14	9,600–10,600
8	15	10,800–11,800
—	16	12,000–12,800
—	17	13,000–13,800
—	18	14,800[b]

[a] U. S. Civil Service Commission.
[b] There is no range within grade GS18.

interesting relationships. (1) Average salaries of those who passed their orals were on the average about $1,100 higher than the salaries of those with only the M.A.; and average salaries of those with the Ph.D. were on the average about $1,300 higher than those who had merely passed the orals.[2] These differentials were somewhat larger for those employed in government service and other economic work, and somewhat less for those employed in teaching. This is surprising in view of the usual opinion that formal graduate education means more in college teaching than in other types of work. (2) Salaries of economists apparently increase as they get more experience. Those who attained their highest academic standing in 1941-45 were getting average salaries about $1,600 higher than those who ended their graduate studies in 1946-50; the 1936-40 group were receiving about $900 more than the 1941-45 group; and the 1931-35 group about $800 more than the 1936-40 group. (3) The salaries of those in government service and other economic work (presumably in business firms, trade associations, labor unions etc.) was about $1,700 greater than the salaries of those in teaching Average salaries in government and other economic work were about equal. (4) The average salaries of men and women were equal in teaching, but there was a differential of more than $2,000 in government service and a differential of nearly $1,000 for all types of employment combined (table 8). Three women reported salaries above $10,000.

[2] In interpreting these comparisons, allowance must be made for the fact that the average age of the master's and oral's groups is undoubtedly lower than that for the Ph.D. group The effect of this age difference, and the resulting difference in amount of experience, would be particularly marked for those who attained highest academic standing in 1946-50.

TABLE 6.—RANGE OF INSTRUCTIONAL SALARIES IN SELECTED COLLEGES AND UNIVERSITIES, 1951–52, BY RANK[a]

	Professors	Associate professors	Assistant professors	Instructors
6 small private institutions, New England and Middle Atlantic				
Minima	$5,200– 7,750	$4,200– 6,000	$3,300–4,600	$3,000–3,500

Market for Economists

With the sizeable graduate enrollments of recent years, and the large number of advanced degrees awarded in economics, the question arises as to whether the market will continue to absorb the annual crop of new economists at present salary levels. For example, since the end of World War II (academic years 1945-46 through 1951-52), about 1,800 Ph.D.'s have been awarded by American universities. The magnitude of this figure can be appreciated when it is realized that this post-war crop represents nearly one-third of all the doctorates in economics ever awarded in this country. In all the years prior to 1945-46 fewer than 4,000 doctorates had been granted.

TABLE 8.—AVERAGE SALARIES IN 1950 OF FORMER GRADUATE STUDENTS IN ECONOMICS AT COLUMBIA UNIVERSITY, BY SEX[a]

Highest academic standing attained and type of work	Men	Women	Men and Women
M.A.	$4,843	$4,455	$4,772

All other	6,186	4,173	5,963
Total	5,854	4,912	5,714

[a] J. W. Angell, *op. cit.* Based on replies from 282 men and 49 women who were regularly employed.

[b] Because of the structure of the sample, no significance should be attached to the fact that the average salary in teaching for women slightly exceeded that for men.

I have no reliable information with which to predict the future market for economists. The following conjectures seem reasonable: (1) that the population of college students will grow in the years ahead, and that opportunities in college teaching will expand; (2) the demand for economists in business, foundations, and other private organizations will increase, though the absolute numbers involved may not be large. (3) there may be a brisk market throughout the world for economists trained in the United States. It is likely, on the other hand, that employment opportunities in the Federal government will grow less rapidly than during recent decades.

Replies to some of my questionnaires suggest that the market—at least through 1952—has been brisk, that graduate students in economics have been finding little difficulty in placement, and that experienced economists have been able to obtain suitable positions in the profession at prevailing salary scales.

A large majority of employers or supervisors of economists in universities and colleges, business firms, and government indicated that the market for economists has been tight. Similarly a large majority of professors in graduate departments of economics stated that most students—both at the master's and doctoral level—have been readily placed. There was some indication, however, of greater placement difficulty during 1951-52 and 1952-53 than in earlier years.

When graduate students in residence in 1951-52 were asked about their career objectives, most indicated that they hoped to have positions as professional economists in higher education, government, or

business. When asked about the prospects of their being able to get the kind of position they hoped for, about two-thirds indicated a high degree of confidence. The answers regarding their prospects were as follows:[3]

	Per cent
almost certain	31
reasonably confident	31
50-50 chance	12
doubtful	9
unlikely	6
don't know	11
Total	100

The relatively strong demand for economists in the past few decades should not be surprising in view of the great expansion of employment opportunities in higher education, government, and business. Whether this demand will continue to grow in the future is uncertain.[4] It seems likely, however, that there will be a fairly consistent demand for persons with the Ph.D. or its near-equivalent. A large proportion of the economists practicing today—including many in high-level positions—have not had formal education equivalent to that represented by the Ph.D. As the supply of Ph.D.'s grows, an increasing proportion of jobs requiring competence in economics will probably be filled with persons having that degree; at the same time it may become more difficult to secure positions in economics without the degree.

Status of the Profession

It would be gratifying for economists to think only of their growing influence and prestige in American life; but candor requires that they also face up to their professional limitations. On many important scientific matters in which society is deeply interested, economists lack demonstrable knowledge. Similarly, on many questions which lie in the realm of values, economists are found to be in disagreement. On

[3] Schedule IX: 140 respondents.

[4] The question of the market for college graduates and the adequacy of the supply of trained professional personnel has become a lively issue in recent years. Prof. Seymour E. Harris in *The Market for College Graduates* (Cambridge, 1949) emphasizes the possibility that we may be on the verge of an oversupply of professional talent. Several other investigations are apparently proceeding from the assumption that there is a shortage of trained professional personnel—especially in the natural sciences and engineering—and are oriented toward finding ways to increase the supply. See: M. H. Trytten, *Human Resources and the Fields of Learning* (A preliminary mimeographed report of a survey under the auspices of the Conference Board of Associated Research Councils, Committee on Specialized Personnel); Commission on Human Resources and Advanced Training, *Plans for Studies of America's Trained Talent,* Washington, 1951; American Council on Education, *The Production of Doctorates in the Sciences: 1936-1948* (mimeographed), Washington, 1951.

these questions, the statements and recommendations of economists sometimes become little more than reflections of personal opinion. As a result, doubt is cast on the validity of all economics and on the usefulness of all economists—sometimes even to the point of ridicule. Indeed, the opinion has frequently been expressed that any interest group can find an economist who will publicly support its position. Since opposing interest groups can also find their economists, the net result of economic advice, as viewed by the public, is sometimes confusion with overtones of bad faith.

There are also other factors tending to lower the prestige of economists. To many people, their main function is to predict business conditions or security prices. Since economists have not been conspicuously successful as business forecasters, the tendency is to repudiate economists altogether. To other people, economists are odiously linked with bureaucracy, or with onerous governmental controls, or with schemes for economic "planning." Still others regard economists as "theorists" in the sense of visionary and impractical men.

A recent study of public attitudes toward various occupations and professions suggests that the prestige of economists is embarrassingly low. In this study, opinion data were gathered through personal interviews with a cross-section of the American public on the relative status of 90 occupations ranging from supreme court justice to bootblack.[5] Included in this list were several learned professions. Table 9 presents a list of selected occupations included in the study with the ranking of each.

In this list, it is noteworthy that "college professor" is placed relatively high with a rank of 7, that most of the learned professions are in the first 25, and that "economist" stands well below *all* the other learned professions included with a rank of 33.[6]

In interpreting these data, however, it should be recognized that 22 percent of the respondents were unable to express a judgment on

[5] National Opinion Research Center, *National Opinion on Occupations, Final Report of a Special Opinion Survey Among Americans 14 and Over Conducted in March, 1947* (mimeographed). This study was conducted under the sponsorship of Professor Paul K. Hatt of Northwestern University who has kindly granted permission for use of the results here. The ranking of each occupation was computed on the basis of a weighted average of the percentage of persons classifying the occupation excellent, good, average, somewhat below average, and poor.

[6] The report on the study states: (p. 4) "If it is found that certain occupational groups have extremely low social status in the eyes of the public, the findings delineate the areas in which remedial public relations are needed. If a certain group (e.g., scientists in general) is found to have quite high social status, that group can infer it has a reasonably good chance to get a respectful hearing from the general public." Also, (p. 21): "County judges, psychologists, sociologists, economists, and bartenders rate higher in the northeast than in other regions."

TABLE 9.—RANKING OF OCCUPATIONS, BY STATUS[a]

Occupation	Rank	Occupation	Rank
U. S. Supreme Court Justice	1	Psychologist	22
Physician	2	Civil engineer	23
State governor	2	Sociologist	26
Cabinet member	4	Owner of small factory	26
Diplomat in U. S. Foreign Service	4	Accountant for a large business	28
Mayor of large city	6	Biologist	28
College professor	7	Captain in the regular army	31
Scientist	7	Building contractor	33
U. S. Representative	7	ECONOMIST[b]	33
Banker	10	Instructor in the public schools	33
Government scientist	10	County agent	37
Minister	12	Railroad engineer	37
Priest	15	Farm owner and operator	39
Architect	15	Radio announcer	40
Chemist	15	Bookkeeper	50
Dentist	15	Garage mechanic	61
Lawyer	15	Milk route man	70
Board member of large corporation	15	Dock worker	81
Nuclear physicist	15	Shoe shiner	90

[a] National Opinion Research Center, *op. cit.*
[b] Of the respondents, 25 per cent rated economist as "excellent," 48 per cent "good," 24 per cent "average," 2 per cent "somewhat below average," 1 per cent "poor," and 22 per cent "don't know."

"economist" and responded "don't know." This percentage was higher than that for any other occupation except "nuclear physicist" and "sociologist." The low status of economists may be explained in part by lack of knowledge.

Conclusion

The economists of the United States are a small heterogeneous group without strong professional consciousness or powerful professional organization. They face public attitudes that are often indifferent and sometimes hostile. Their status as viewed by the public is lower than that of other learned professions. Nevertheless, economists exert an important—and probably growing—influence in American life—an influence that is entirely disproportionate to their numbers or to the offices they hold. This influence is due primarily to the increasing public interest in economic affairs, an interest which has grown out of this generation's experience with depression, war, inflation, high taxes, enlarged scope of government, labor conflict and the world-wide threat to the capitalistic system itself. The advice of technically trained economists is sought by government, private business firms, trade associations, labor unions and other groups. Economists frequently appear as expert witnesses before Congressional Committees and public boards. Because economics has become a leading study in schools and colleges,

and because citizens of all classes have become intensely interested in economic affairs, economists are able to exert significant influence through their teaching, writing, and lecturing. Frequently the research studies and theoretical investigations of economists lead the way to new public policies in fields such as taxation, banking, anti-trust, labor legislation, foreign trade, or national defense.[7]

It is not to be inferred, however, that most economists are sitting at the right hand of policy-makers guiding the destiny of the country day by day and in detail. The great majority of economists work in relatively obscure and even humble jobs as teachers, as research workers, and in various minor posts as administrators or research assistants. Few of them ever see, much less advise, Senators or Cabinet Members or leading businessmen. Only a few economists ever occupy positions of direct power and influence or are consulted directly by men of decision. Yet the influence of all is felt and their combined impact is very great. Collectively they are custodians of our accumulated economic knowledge from the past, they are scholars continuously extending this knowledge and advancing new ideas, they are teachers patiently disseminating this knowledge, and they are consultants applying it to particular policy problems. The role of those few economists who are in direct contact with policy-workers should not be over-emphasized. They serve as one link by which the knowledge of the entire profession is transmitted to those who can make use of it. The other—and perhaps more important link—is education in all its ramifications. It is primarily through education at all levels that the knowledge of professional economists is brought to bear on social problems. I know few economists who are not also educators in some sense.

The recruitment, selection, and education of the individuals who are to join this profession is a matter of grave concern not only to the profession itself but also to the entire nation. The future of our kind of society depends largely upon our ability to manage economic affairs successfully in relation to our values. It is vital to the future of our society that successive generations of economists be trained who will have the technical skills, the broad perspective, the judgment, the leadership, and the sense of social responsibility necessary to advance the frontiers of knowledge in the field and to translate this knowledge into practicable solutions for social problems. The remainder of this study will be devoted to a discussion of the education of professional economists.

[7] For an interesting discussion of the role of economists, see: "The Economists," *Fortune*, Dec. 1950, pp. 108-112.

Chapter 4

OBJECTIVES AND STANDARDS IN GRADUATE EDUCATION

On the general objectives of graduate education in economics and the standards which derive from these objectives, I have consulted with many economists, employers of economists, graduate students, and others, and have observed graduate education in operation at many universities. I have tried to formulate the objectives and standards with a view to their practicability and acceptability to a considerable body of opinion in the profession. I cannot claim, however, that this discussion represents an authoritative statement of the views of the entire profession or of any large segment of it. It represents only my own view of the matter reached after wide consultation.

In some respects my consultation on the subject of objectives and standards was disappointing. I found that objectives and standards actually operative cannot easily be communicated to an outside observer. Faculty members have difficulty not only in achieving an objective view of the standards which they actually employ but also in expressing these standards in concrete and specific terms. An observer, on the other hand, finds difficulty in interpreting the objectives and standards of any given institution on the basis of its practices which he can know only superficially and remotely. The actual objectives and standards of an institution are to be measured not by the verbalizations of professors, by statements in glossy brochures, or by the casual observations of an outsider, but by the day-by-day experiences of students—by the courses, the examinations, the dissertations, and the actual judgments of advisers and examining committees.

I was impressed nevertheless by the fact that there are many social and institutional forces making for relative uniformity—at least in the *formal* objectives and standards actually operative in various universities. First, graduate departments of economics are ordinarily located in graduate schools which attempt to establish relatively uniform procedures and standards as laid down by the Association of American Universities and other accrediting agencies. Second, the migration of staff members from one university to another—as they go from their own graduate schools to posts in other universities or as they move from one university to another—makes possible continuous comparisons of the standards of various universities. Third, the less renowned universities, which are usually eager to gain in prestige and to avoid any suspicion of low standards, characteristically try to fol-

low the example of leading universities, and are extremely conservative as regards deviation from standard practice. Fourth, the lowering of standards by any institution becomes known within the profession and places that institution in a position of disrepute which it will eventually try to correct.[1] Fifth, attempts to raise standards very much above generally accepted levels are defeated in most institutions by the fear of adverse effects on student enrollments. All these levelling factors have resulted, I think, in fairly similar standards and fairly uniform conceptions of such terms as "master's degree," "Ph.D.," "doctoral dissertation," "graduate student in economics," etc.

I do not mean to imply that there are no differences among universities in objectives and standards, or in quality of graduate instruction, but only that there are strong nation-wide tendencies toward the institutionalization of practices and of formal objectives and standards.

Where differences exist I believe they are due partly to differences in the quality of students attracted to the various institutions. It is easy to say that each department should admit only those students who have demonstrated a high level of ability. But if a department which is geared to do graduate work, which thinks of itself as a graduate department, and which possibly needs graduate assistants fails to attract students who meet this abstract standard, it will be strongly tempted to lower admission requirements. Having admitted substandard students such a department will hardly want to deny all of them degrees. But more important, the faculty's concept of a proper standard will be influenced by the performance of the actual students they know. Their concept of a "good student" or an "average student" will be modified. Accordingly, the admission of students of low quality will have the ultimate effect not only of lowering operative standards but also of lowering abstract or ideal standards as well.[2]

General Objectives

Graduate education in economics, in this country, consists of a program of studies which can be completed in a minimum of three years by a well-prepared and capable student. The program culminates in the award of the Ph.D. However, only about one out of 10 students

[1] This corrective process is, however, by no means automatic or inevitable because the faculties of some departments do not have enough contact with the profession-at-large to make the force of professional opinion effective.

[2] It is in this way that the master's degree may have become depreciated as a result of the pressure on secondary teachers to earn such a degree; similarly the Ph.D. may have been depreciated by the pressure on college teachers to take doctorates. The result of such pressure was the admission to graduate school of many persons who could not meet accepted standards, thus to lower the average quality of graduate students, eventually to lower both operative and ideal standards.

who enter graduate study in economics ever receive the Ph.D. The others drop out at some earlier point—some after only a few months of graduate study, others at the completion of the master's degree, some prior to the preliminary examinations for the Ph.D., and some prior to completing the doctoral dissertation.[3] Many of those who do not push through to the Ph.D. nevertheless pursue careers as economists or careers in which economic education is useful. Thus, in the graduate program in economics, various individuals spend different amounts of time—the amount in each case depending upon objectives, capabilities, and personal circumstances.

The primary objective of the great majority of these persons is to prepare themselves for positions in which they will use their economic education. In this sense, it is vocational or professional education.[4]

Table 10 presents data on the immediate and longer-range career objectives of respondent graduate students who were in residence during 1951-52. These data indicate that about one-fourth of the first-year students are headed toward higher education, another fourth toward government, and more than a third toward business—many of the latter hoping for executive or operating jobs. In the longer-run, somewhat more of the first-year students are hoping for jobs in higher education and somewhat fewer for jobs in government and business. The advanced graduate students, on the other hand, are predominantly directed toward higher education. For most of them government and business are second choices. My conversations with graduate students at many institutions revealed, however, that many of those who prefer teaching do not consider it a strong preference. The figures on career objectives of present graduate students (table 11) correspond closely with the actual positions held by former graduate students in economics.[5]

Many observers deplore the tendency of students and others to look upon graduate education as vocational training. In particular, they object to the specialization that sometimes results from efforts to train people for specific jobs. They argue that the purpose of graduate work

[3] For estimates of student mortality, see p. 92.

[4] "The graduate school has become a professional, even a vocational, school giving professional and vocational training in the same spirit as the law school, the medical school, or the business school. It receives the products of the liberal arts colleges and prepares them for certain trades, industries and professions. It manufactures technologists whether in philology or physics. It leaves general education to the college. If it concerns itself with research, it is only because, as a teaching problem, research activity is one part of the training of many kinds of technologists, but by not means of all of them." Howard Mumford Jones, "Post-War Planning for the Graduate Schools," paper presented at the 17th annual meeting of the Deans of Southern Graduate Schools, October 19, 1943, p. 11.

is to produce scholars—persons who have a deep and broad knowledge of their subject and of its development, who are intent upon a life of study and investigation, and who are interested in contributing to the advancement of the field. They argue that while it is well for scholars to find jobs, yet scholarship should not be compromised in the interests of vocationalism. In opposition to this point of view, others hold that scholarship is highly desirable in its place but that there are many specialized technical jobs for which competent people must be trained and that one of the tasks of graduate schools is to provide this training.[6]

Most economists are not perturbed by this conflict of objectives. On the whole, they believe—at least in their field—that the objectives of scholarship and of vocationalism can be reconciled. They believe that the best preparation for professional work in economics consists of education having as its objective the development of scholars. They are almost unanimous in their condemnation of specialized programs of study with vocational emphasis. They believe that the task of graduate education is to produce scholars who have an understanding of the fundamentals of economics and the tools of research in the

field. They feel that individuals with this equipment can adapt to specific vocational tasks easily and quickly. They are under no illusion that all graduate students will in fact become scholars, but they are firm in the conviction that education designed to produce scholars will in the end also produce the most capable technicians.

They are led to this conclusion partly by the tradition of economics, which is a scholarly tradition, and partly by the nature of the subject matter of their field. Economics is largely a study of the economic system. The economic system is a complex mechanism, all the parts of which are interdependent and no part of which can be grasped until it is understood in its entirety. It is an evolving system, the present form of which cannot be understood without reference to its prior development. And ideas and theories about the system cannot be fully understood without reference to the intellectual heritage from which they have emerged. For these reasons, most economists believe that a person who wishes to function successfully in the profession—whether in a governmental bureau, a business firm or a college—will be well-advised to aim for broad and fundamental knowledge of the field such as would be obtained by one who expects to devote his life to scholarly research. It is true that not all professional activities of economists

require great erudition. Not everyone need be, or can be, a great scholar. But all require knowledge of fundamentals and breadth of understanding.

There are other impelling reasons for this emphasis upon fundamentals. First, it is recognized that a finished economist cannot be produced in the few short years of a graduate school program. Mastery of this field, like any other scholarly field, requires a lifetime—not one to three years. The problem of graduate education, therefore, is to concentrate on those aspects of the subject which can best be acquired through formal education and which will best launch the student on a lifetime of self-education. The problem is to teach people how to learn, not merely to teach them specific subject matter. It is precisely the fundamentals—e.g., economic theory, economic history, history of ideas, and research techniques—which are most efficiently acquired through formal education and which provide the groundwork for later self-education. As one eminent businessman wrote in a letter to me:

> One of the great dangers of the present day is the unwillingness of technical students to realize that they are merely learning the rudiments of their profession and that once they get into practice they will be living the history of their profession rather than merely utilizing what they learned during their training period.

Second, in their graduate years students often do not know precisely what work they will follow. Therefore it is best at that stage to concentrate on those aspects of the subject having wide applicability. This point is strengthened by the fact that many economists shift in the course of their careers from one kind of employment or activity to another. Indeed, the frequency and the ease with which economists shift back and forth between teaching, government, and business is further evidence that the work of economists—wherever they may be placed—has a significant common element and that much the same kind of formal education is appropriate for all economists regardless of their specific jobs.

All of these considerations lead to the conclusion that, even though the employment opportunities of economists are expanding into new fields, the formal education of economists should place emphasis on fundamentals and scholarship.[7]

[7] Some of my critics have argued for changing the emphasis here. For example, one writes: "While I should agree upon the need of a common core for all, I think I should advise different emphasis for various groups. For those going into undergraduate teaching I should put a good deal more emphasis upon economic history, history of thought, and philosophy and somewhat less emphasis upon quantitative techniques. Whereas for those going into government service I should put a good deal more emphasis upon these quantitative techniques."

Standards

It is always tempting when considering educational philosophy to propose uniform and detailed minimal standards which all students of a given type or all candidates for a given degree should attain. Such uniformity may be possible in a field like accountancy, but it is probably not possible—and surely not desirable—in economics. There is need for economists of widely varied interests, capacities, and skills. Some should pursue historical studies, others should explore points of contact with social psychology; some should study the steel industry, others the Soviet economy; some should investigate the theory of employment, others linear programming; and these various specialists should interact with one another in mutually helpful criticism.

There can even be diversity among universities. It is not necessary for each one to provide opportunities for formal study in all of the fields or from all points of view: some can specialize in one direction and some in another according to their facilities, staff, and financial means. The only problem is to insure for the nation as a whole that a flow of competent persons will be forthcoming to enter all of the various sub-specialties of economics.

The need for variability suggests that it would be unwise for any professional association or accrediting agency to attempt to prescribe uniform standards or requirements for all graduate students of economics at each level. Economics as a discipline has not coalesced to the point of having an acknowledged set of requirements which every student must meet before he is eligible for a degree or for a license to practice. Yet it is possible and reasonable to advance certain standards to be applied to graduate students in economics.

In the remainder of this chapter, I shall attempt to formulate minimal standards that should be attained by candidates for the Ph.D. and for the master's degree at the time the degrees are awarded. In formulating these minimal standards, I have tried to avoid wishful Utopianism. I have attempted to consider the realistic conditions under which most graduate faculties work. Yet I feel that the minimal standards suggested are higher than those actually in operation in many universities. In my judgment, if these standards were scrupulously followed, the requirements for advanced degrees in economics would be raised perceptibly.

I should emphasize that these standards represent my own personal view arrived at in consultation with many interested persons. In no sense do they represent the official position of the American Economic Association or of any other group.

Standards for the Ph.D.

I shall try to express the standards to be met by a Ph.D. candidate under five headings: (1) personal qualities, (2) knowledge, (3) abilities and skills, (4) professional orientation and motivation, and (5) capacity for growth and adaptation. These standards are intended to apply at the time the degree is awarded, though of course they may influence standards for admission to, and advancement in, graduate study.

1. *Personal qualities.*
   - (a) *Intelligence.* In general "intelligence" or "scholastic ability," a Ph.D. candidate should rank at least among the top 15 per cent of all college graduates. This suggests that he should be the kind of person who might have earned mostly A's and B's in undergraduate work in a good university or college, or who might have been among the top 15 per cent of all college graduates in his score on appropriate intelligence tests.[8] This standard is expressed in terms of undergraduate grades or intelligence tests because course grades in graduate work are notoriously undiscriminating.
   - (b) He should be a person capable of intellectual maturity and judgment.
   - (c) He should have the emotional stability necessary to function in the kinds of positions economists are called upon to fill, i.e., he must be sufficiently adjusted that he can be conscientiously recommended for a position.
   - (d) He should be a person of integrity and good character.
2. *Knowledge.*
   - (a) *Common Core.* Although there is, and should be, great diversity among economists in their intellectual equipment and interests, neverthless there is a substantial nucleus of subject matter which should be common to all economists regardless of their special interests. It is this common core which should bind the profession together and should enable economists

[8] The upper 15 percent appears to be somewhat above current standards. As shown by Dael Wolfle and Toby Oxtoby, "The average person earning a bachelor's degree scores about 126 on the Army General Classification Test scale. About 10 percent of the total population earns a score this high. The average graduate student gets a score of around 129. About 7 percent of the total population does as well. The average Ph.D. in science makes a score of approximately 138. Only about 2 per cent of the total population makes a score that high." ("Distributions of Ability of Students Specializing in Different Fields," *Science*, Sept. 26, 1952, p. 311.) These figures suggest that the Ph.D. in science are generally in the upper 20 percent of all college graduates.

of all types and persuasions to communicate with one another. This common core consists primarily of economic theory including value, distribution, money, employment, and at least a nodding acquaintance with some of the more esoteric subjects such as dynamics, theory of games, and mathematical economics. Other important parts of the core are economic history, history of economic thought, statistics, and research methods. No one has a claim to a Ph.D. in economics without a rigorous initiation into these fields.

(b) *Special fields of economics.* Each candidate for a Ph.D. should be prepared in two to four special fields of economics in addition to the common core. He should present one of these fields as his major specialty. In that field he should have detailed and comprehensive knowledge. In each of the other special fields, his preparation should be equivalent to that which could ordinarily be acquired through a one-year graduate course and supplementary independent study. In case a student wished to present a field from the common core as his special field, e.g., economic theory or statistics, he should be permitted to do so by presenting evidence of mastery beyond that required for all students as part of the common core. The special fields should not be thought of as distinct and separate from the common core. Rather, they should be regarded as a vehicle for bringing the various concepts and methods of the common core to focus on a particular set of problems.

(c) *General knowledge of the entire field of economics.* Because the field of economics is broad and complex, it is not feasible for Ph.D. candidates to achieve intimate knowledge of every part of the field. Yet, the economy is a system, all the parts of which are interrelated and no part of which can be fully understood without knowledge of the whole. Regardless of his specialty, therefore, an economist is likely to find that some knowledge of most aspects of the subject will be useful if not indispensable. Every economist, regardless of his special field, probably should have some acquaintance with international economics, public finance, banking, agricultural economics, industrial organization, labor, insurance, business cycles, transportation, public utilities, etc. The need for this general knowledge extends to the various fields of business such as management, investments, corporation finance, personnel, accounting and marketing. Candidates for the Ph.D.

should demonstrate breadth of knowledge in many areas of economics outside the core and outside their special fields. Their knowledge in each area should approximate that which could be obtained by a careful reading of elementary "survey" textbooks in each of the fields. However, it is not to be inferred that they should be required to read these books or to take a multitude of elementary courses. It is suggested only that they should be required to gain breadth of general knowledge in economics. Much of this general knowledge is more or less spontaneously picked up by alert and intellectually curious graduate students as they enter into discussions with other students, hear lectures, look up factual points referred to in their reading, scan the news about current economic problems, etc. Yet the required breadth probably will not be acquired by most students without some special effort.

(d) *Research tools.* There are many research tools that can be put to the service of economics, among them, foreign languages, mathematics, accountancy, law, public opinion polling and other socio-psychological techniques, use of historical records and archives, and others. (Statistics is omitted here because it is regarded as a special field of economics included in the common core.) Each candidate should have enough knowledge of all these tools to understand how each can be useful. Indeed, a case could be made for requiring all Ph.D. candidates to achieve considerable competence with each of these tools. Yet this seems wasteful and unnecessary since not all economists use all of these tools. On the other hand, it is important that a steady flow of economists be produced who do have competence in each of these fields. For example, while it may not be necessary for every economist to have a knowledge of mathematics, it would be desirable to turn out many who can use mathematics. While it may not be necessary for every economist to know Russian or German or Chinese, it would probably be useful to have some with knowledge of these and of other languages. I should argue, therefore, that every Ph.D. candidate should be required to demonstrate the ability to use at least *one* important research tool that is relevant to his special interests. This means more than the passing of a perfunctory examination such as the present foreign language examinations have become. It means that the student must demonstrate ability to use at least one research tool effectively. If

the tool is a language, he must be able to read difficult materials rapidly and accurately. If the tool is mathematics, he must be able to read mathematical literature with facility and to use mathematics in his own research—not merely to have a superficial knowledge of "mathematics through calculus," etc.

(e) *Fields outside economics.* Broad as is the field of economics, the candidate for the Ph.D. has need of general knowledge—in some cases quite specific knowledge—outside economics.[9] He needs to know something of logic, scientific method, ethics, world geography, world history, history of ideas, industrial and agricultural technology, law, government, international relations, psychology, and current social and political events. Much of this background he may have acquired in his undergraduates years and much of it he may have absorbed through general reading and daily living. But not all of it comes to him automatically. He should specifically be required to repair gross defects in his general intellectual background before he is awarded a Ph.D.

3. *Abilities and skills.*

(a) *Reading.* A candidate for the Ph.D. in economics should be able to read with comprehension any literature in the common core except literature involving higher mathematics or some unusual technical apparatus. He should be able to understand its relevance to problems and issues. He should be able to place it in the stream of the history of ideas. He should be able to interpret it to others and to discuss it intelligently. If his special field is one in which mathematics or other unusual technical apparatus is commonly used, he should be able to read *all* literature in that field with comprehension. In fields of economics outside the common core and his special field, he should be able to read with comprehension all except the more difficult literature.[10]

(b) *Writing.* The candidate for the Ph.D. should be able to

[9] Cf. Association of American Universities, "Report of the Committee on Graduate Work," *Journal of Proceedings and Addresses,* 1948.

[10] It has been suggested that a Ph.D. should be able to read the *American Economic Review.* This journal is mentioned because the articles pertain chiefly to the leading sub-fields in economics and are chiefly non-mathematical. Some argue that this is too low a standard in the sense that any economist should be able to read more difficult literature than is in the *Review.* I have been told, however, by several experienced professors who hold Ph.D.'s in economics that this is too high a standard which they themselves would be unable to meet.

write either brief or extended discourses on subjects pertaining to economics. He should be able to write for both technically trained and lay readers. This writing should be logically organized, clearly expressed, and formally correct. It is perhaps too much to ask that it also be effective and interesting. The ability to write logically, clearly, and correctly is an essential part of the equipment of an economist, and every candidate should be required to meet this standard before receiving a Ph.D. Indeed, present requirements regarding literary ability are probably not as high as they should be. One of the most persistent criticisms by employers is that many economists—even those with the Ph.D.—lack adequate literary skill.

(c) *Speaking.* In almost every activity which engages professional economists, speaking ability is an asset. This is true not only in education but also in business and government. In the latter two fields, the ability to speak is needed more often in discussions, conferences, and negotiations; whereas in education it is needed for classroom presentation and public lectures. But in all of these employments, an economist's effectiveness derives partly from his facility in oral expression. In view of this, a Ph.D. candidate should be able to speak clearly and coherently before a class, a seminar, a public audience, or a committee. He should be able to do this before both technically-trained economists and lay groups. He should also be able to conduct himself effectively in conference or in informal discussion. Ability to participate effectively in informal discussion is perhaps the most important of the speaking (and listening) skills. The give and take of discussion is one of the best means of generating economic ideas and of subjecting them to the test of criticism and competition.

The standard for speaking should not be set too high, because ability in this field—perhaps even more than others—comes through experience. Yet the candidate should show sufficient facility to indicate that he is capable of adequate development. The standard for writing and speaking should be considered jointly. If a student is capable in written expression but weak in oral expression, or vice versa, the weakness in one can be partially offset by strength in the others. There are professional activities in which the use of each mode of communication is predominant. But if the student

is conspicuously deficient in both, there is grave question whether he can function effectively as an economist, and it is doubtful if he should be considered for a Ph.D.

(d) *Teaching*. At the completion of his Ph.D., the candidate should be prepared, at least in terms of mastery of content to teach the following courses: principles of economics, the first undergraduate course in his special field, and (given time for adequate preparation) intermediate economic theory. This standard should apply to all students—regardless of whether they intend to enter teaching as a career. A man who is unable to meet this standard will not be qualified for other professional positions ordinarily open to Ph.D.'s in economics.

(e) *Research*. Because research activities are so varied, it is difficult to define standards in this field meaningfully. Traditionally the Ph.D. has been regarded as a "research" degree, and the primary purpose of the educational program leading to the degree has been to train research scholars. It has been held that the dissertation should be a demonstration of the candidate's ability to make "important and original contributions to knowledge." This has implied that a candidate for the Ph.D. should be able to function at a very high level in research. The phrase "important and original contribution to knowledge" is still found in many graduate school catalogs, but in most departments of economics it does not form part of the operative standards or at most the phrase remains with the word "important" deleted. Only occasionally, in fact, does a dissertation turn out to be a significant contribution to knowledge. Today, the young Ph.D. is regarded not necessarily as a person who has made significant contributions to knowledge but rather as one who has (or should have) become generally oriented in the field and who has learned something about its basic methods of research.[11] It may be hoped that he will some day produce important research but that is not to be expected immediately. Even this hope is not held too sanguinely. As is well known, only a minority of Ph.D.'s ever produce important original research.

It is obvious, then, that a return to the older concept of the Ph.D. would represent a drastic tightening of standards

[11] Cf. Elbridge Sibley, *The Recruitment, Selection and Training of Social Scientists*, Social Science Research Council, New York, 1948, p. 83.

which would eliminate the majority of candidates. No one seriously proposes this. On the other hand, no one wishes to abolish all standards regarding competence in research. Perhaps the following are the things every candidate should be able to do before he is awarded a Ph.D.: (1) to utilize economic theory in analyzing the consequences of changes in demand, in supply of factors, in technology, in industrial organization, in governmental policy, etc.; (2) in some of the simpler cases, to devise procedures for testing the hypotheses suggested by theory; (3) to serve as a useful assistant or as a member of a research team, assuming responsibility for carrying out substantial blocks of work under the general direction of a mature research worker; (4) to initiate, design, and execute limited studies involving the collection and interpretation of primary data or the analysis of data collected by others. If these abilities were to be rigorously required, a substantial raising of present minimal standards would be involved. Nevertheless, these standards are more modest and more realistic than the older standard which purported to require an important and original contribution to knowledge. The obvious conclusion is that we cannot hope to make every Ph.D. into a Wesley Mitchell or a J. M. Keynes. We can, however, insist that they know something about the basic methods of research in economics and that they be able to apply these methods in relatively limited research situations.[12]

(f) *Writing for publication.* There is some question as to whether a condition for granting the Ph.D. should be the ability to write articles, reviews, monographs, books, etc., of a quality suitable for publication in recognized journals or through commercial channels. We have already considered literary ability and it is assumed that the candidate should be able to write logically, clearly, and correctly. The question here is whether he should be able to produce works the content of which would merit publication in a professionally reputable organ.

The traditional answer to this question was affirmative. This was part of the theory underlying the rule of mandatory publication of dissertations. But this rule has by now virtually disappeared and today there is little emphasis on pub-

[12] The requirements concerning teaching and research might be considered jointly in the same way as the requirements regarding speaking and writing. Excellence in one might offset deficiency in the other.

lication as a requirement in connection with the granting of the Ph.D. There are some, however, who decry the passing of the publication requirement and the standard it represented. At a few universities, an attempt is being made to institute another standard, namely, that a candidate for a Ph.D. should be able to write an article acceptable for publication in a leading professional journal. All admit that not every candidate could in fact get such an article accepted, if for no other reason, because there are simply not enough journals to carry articles by each year's crop of Ph.D.'s. But the proposed standard is not that the candidate should actually *publish,* but only that he should be able to write an article of approximately the same quality as those which are published. Others have proposed that a candidate should be able to write a publishable review of a book in his special field, still others that he should be able to write an elementary textbook in his field.

My judgment on this question is that publication has been grossly over-emphasized. For the same reason that most Ph.D.'s cannot be expected to make important and original research contributions, most of them cannot be expected to turn out writing of a publishable quality. Few dissertations are published either in entirety or in article form, and in fact many recipients of Ph.D.'s never produce significant publications. To hold rigorously to a publication requirement could have only two effects—both of them undesirable: either the drastic raising of standards so that only a fraction of the present flow of candidates could be awarded degrees, or the proliferation of second-rate publications and a drastic lowering of the standards required for publication. As it is, the emphasis on publication as a means to prestige and professional advancement has the undesirable effect of encouraging a flood of unimportant and unconsidered articles, papers, pamphlets and books. How much better if, in graduate school, students were led to become more reticent and self-critical concerning their intellectual output instead of being encouraged to publish whether or not they have something important to contribute.

But merely to say that the encouragement of publication has been overdone does not dispose of the problem of what standard to set for the Ph.D. candidate regarding writing. I believe that he should be able to do at least the following kinds of things: (1) write an acceptable memorandum,

addressed to his non-economist superior regarding some recent development in his field, reporting on a research project in which he has been engaged, or stating his views on a public policy proposal pertaining to his field; (2) write a short statement on some technical point or some recent event for the use of undergraduate students; (3) write a report for technically-trained readers on a research project in which he is engaged; (4) assist in preparing testimony to be given before a legislative committee; and (5) write critical analyses or syntheses of current literature in his field. In the above list, I have refrained in each case from indicating that he should be able to produce writing of a quality suitable for publication. I had in mind, however, that the quality should be very close to publishable. Indeed, I might concede that he should be able to write acceptably for publication in a house organ in the business firm where he is employed, in a specialized government document, in the kind of academic publications usually labeled "Studies In———." Perhaps he should be able to write a book review that would be acceptable for publication in a leading journal. But I believe it would be unrealistic to expect every Ph.D. candidate to be able (either immediately or at a more remote time) to contribute articles to a leading journal, to write for periodicals having national circulation, or to write books for commercial publication.

4. *Professional orientation and motivation.*

(a) The candidate for the Ph.D. should exhibit a serious interest in economics, a will to advance his knowledge of the subject, and a desire to make contributions to it. He should be dedicated to a life of study and investigation in the field. He should set high standards for his own professional work, and should hold shoddy or intellectually dishonest work in contempt.

(b) He should be imbued with the values that are traditional with scientific workers in all fields: namely, freedom of inquiry, freedom of expression, respect for logic and objective evidence, the obligation to report findings fully and accurately and to submit them to criticism, the desire to advance knowledge regardless of its immediate utility, and a concern to utilize the findings of science in ways that will benefit mankind. This value system is difficult to apply to economics, a discipline which operates in an area that bristles with

interest groups and ideologies. Economists, moreover, are part of the society they study. They are themselves members of interest groups and believers in ideologies. Therefore, scientific integrity and objectivity is for them much more difficult than for chemists, astronomers, or anthropologists. This means that the problems of scientific integrity and objectivity, which can almost be taken for granted in other fields, must be handled with special care in economics. An economist who wishes to follow the canons of science must be concerned with freedom of inquiry and freedom of expression even for those whose ideas he does not accept; he must have respect for logic and evidence even when they lead to conclusions he dislikes; he must report findings fully and accurately regardless of the interests that may be affected; and he must be interested in the advance of economic knowledge all along the line whether or not it supports his special views. It becomes incumbent upon economists, therefore, to attempt to understand their own ideological biases and to guard against them in their professional work. Economists must be constantly on guard lest they fail to distinguish between their beliefs and objective fact, or lest they subconsciously select evidence to fit their beliefs. The graduate school is the place where much can be done to help economists understand the perils of ideological biases and the meaning of detachment and objectivity.

This does not imply that graduate students should be decontaminated of all ideologies or that they should be encouraged to take passive or neutral positions on social issues. It implies only that they should become aware of the difference between belief and fact, that they should recognize their own personal biases, and that they should understand the nature of scholarly integrity.

5. *Capacity for growth and adaptation.*

Graduate study should be directed toward acquiring the fundamentals of the subject and toward erecting an intellectual foundation on which further building will be possible. In accordance with this objective, the graduate years should not be devoted to intense specialization. That is to come later. It is to be expected that in 10 or 20 years, after a candidate has acquired years of experience and self-education, he will be able to achieve many things which are beyond him as he emerges from graduate school. It is possible that

standards for the Ph.D. should be stated in terms of the kind of economist the candidate can reasonably be expected to become in 10 or 20 years, rather than in terms of his actual accomplishments to date. At any rate, it is evident that one of the standards should be capacity for satisfactory professional development. This capacity must be measured in terms of his motivation, initiative, and energy as well as his intellectual equipment; and in terms of his ability to adapt to new developments in the field as well as to carry forward present modes of thought.

Care must be exercised in applying this standard. It sometimes opens the way to rationalized laxity on the part of examining committees. It is easy for them to say, when faced with the unpleasant task of appraising a questionable candidate: "He isn't very strong, but he may develop given time for greater maturity and experience." I believe that this is usually sheer rationalization. In most cases, those candidates who do not meet the standards for the Ph.D. are the very ones who do not have the capacity for growth. Success in the graduate period is the most reliable index of the intellectual and motivational qualities that will lead to professional growth after the graduate years.

Conclusions Regarding the Ph.D.

I have presented a long array of minimal standards which might be employed in appraising candidates for the Ph.D. It is obvious that such an array of standards should not be applied mechanically. It is equally clear that it would be foolish to reject some candidate who failed to meet every single standard. For example, one might easily pass a candidate whose speaking ability was sub-standard. As one professor commented, "I would gladly grant a Ph.D. to a deaf mute if he had the required intellectual qualities." Similarly, one might not wish to hold rigidly to standards regarding writing ability, teaching, general knowledge, personal adjustment, or professional orientation. Rather, all of the standards should be regarded as a unified set of criteria by which candidates are to be judged. Ideally, a profile might be constructed for each candidate indicating his score with respect to each of the standards. Any candidate would be expected to score higher in some respects than in others. If a given candidate should fall below minimum on one or a few counts, this might be overlooked if his score on others were distinctly above the minima. However, none of the standards is unimportant or to be passed over lightly; hence, any candidate who falls below the minimum in any one respect should

fail unless he shows genuine distinction in some other equally important area. With some of the standards, of course, no compromise should be made. This would be true especially of general intelligence, motivation, preparation in the common core, preparation in the candidate's special field, and reading ability.[13]

These standards have been designed on the assumption that little differentiation is to be made between those students who are expecting to enter college teaching and those who are pointed toward research, consultative, and administrative positions in business, government, or research organizations. It has been frequently suggested that these two types of students should be set apart and given different types of education.[14] There is strong evidence that members of the economic profession do not favor such differentiation, although some would argue for more attention to the training of college teachers. Out of 27 institutions reporting, only 4 indicated that any effort is being made to differentiate the two types of students and these indicated that this was done only by means of informal adjustments in the programs of individual students. When graduate professors were asked to give an opinion on the desirability of such differentiation, the overwhelming majority were opposed. They felt that the diversity of student objectives is no handicap to the instructional program, and that the several types of students should have virtually the same educational programs.[15] The professors were almost unanimous in their opposition to the proposal that the graduate school should be divided into two units, one for the training of prospective college teachers and the other for the training of research workers. In short, most graduate professors feel that the task of the doctoral program is to produce *economists* who will have the basic equipment and flexibility to function in any of the vocational fields open to economists. They feel also that research training is essential in the education of college teachers.

On the whole, the above array of standards has been expressed in terms of what the candidate should know and be able to do rather

[13] One of my critics writes: "I have very mixed feelings regarding these standards. Sentence by sentence I agree with almost everything you say; yet as a whole I am somewhat uneasy. (a) You seem to be applying a double standard—an ideal one for things that can't be checked and a more realistic one for things that can be, (b) these are not in any meaningful sense minimal standards—though some individual ones are, (c) in the standards regarding knowledge, you ask too much and too little—too much breadth and too little depth."

[14] See, for example, Howard Mumford Jones, *Education and World Tragedy*, Cambridge, 1946.

[15] While most departments are oriented largely toward preparing college teachers, a few are attempting to specialize in training civil servants or economists for business. I do not mean to oppose such specialization so long as it does not result in inferior or narrow education.

than in terms of abstract qualities such as initiative, imagination, creativity, perseverance, self-discipline, critical facility, etc. This is not to imply that these qualities are unimportant. Quite the contrary. They are simply subsumed under the standards which are expressed, so far as possible, in operational terms.

To summarize the standards suggested, I can hardly do better than to quote from a report of the Committee on Professional Training of the American Chemical Society on the "Philosophy of Graduate Training at the Ph.D. Level:"[16] "The objective of graduate training at the doctoral level is to stimulate and develop in properly selected and qualified students the power for creative achievement in their chosen fields. In order to accomplish this these students must be given a thorough grasp of the fundamental sciences underlying their general fields of special interest. Their ability to recognize unsolved problems should be developed and they must be trained in the effective application of modern methods and techniques to the solution of these problems. They should be trained in logical thinking and should be helped to develop the ability to express themselves clearly and forcefully both orally and in writing. Their interest and enthusiasm for research and creative work should be fostered."

Standards for the Master's Degree

Opinions in the profession about the objectives of the doctoral program and the significance of the Ph.D. are much more clearly crystallized than those about the master's degree. There is a tendency in many quarters, quite mistaken I think, to belittle the master's degree, to regard it as an unimportant vestige, or even to eliminate it. It is spoken of as "a fifth year of undergraduate work" or "as a consolation prize" for those who can't qualify for the doctorate, or as a "catch-all" degree for those who want a little specialized graduate training, or as a "union card" for secondary school teachers. It is true that the master's degree is sometimes all of these things, but it does not follow that it is nothing more or that it should be despised, ignored, or eliminated.

A large part of the actual graduate teaching of economics is bestowed upon students who will never receive the doctorate. A great majority attend graduate school for only one or two years. The number of master's degrees granted each year is four or more times the number of doctorates awarded, and there are many students who receive no graduate degrees whatever. The great bulk of graduate study, then, is done in the earlier years or, roughly, at the master's level. Clearly,

[16] *Chemical and Engineering News*, Jan. 19, 1948, p. 167.

we should consider carefully the program in the earlier years of graduate study, the role of the master's degree, and the standards it should represent.

The many graduate students who do not attain the doctorate, and for whom the master's degree is likely to be a terminal degree, may be divided into six groups:[17]

1. Prospective secondary school teachers.
2. Those interested in specialized vocational training, e.g., security analysis, market research, specialized statistical work, etc.
3. Those merely adding a fifth year of education with career plans indefinite.
4. Prospective teachers in junior colleges or colleges who do not intend to try for the doctorate.
5. Those hoping to enter professional work as economists in government or business without commitment to a narrowly specialized field.
6. Those who hope to earn the Ph.D., many of whom will fall by the wayside before attaining the doctorate for reasons of intellectual deficiency, lack of motivation, inadequate finance, poor health, attractive vocational opportunities, etc.

On the basis of an inquiry to graduate professors and from data on the actual career objectives of graduate students (see table 10), I would judge that the percentages of first-year graduate students in each class would be about as follows:

Prospective secondary teachers	5%
Specialized vocationalists	5
Fifth year of liberal education	15
Teachers in higher education	10
Prospective economists in business and government	30
Prospective or hopeful candidates for the Ph.D.	35
Total	100

It may be properly argued that not all of these classes of students should have identical educational programs. Yet it can also be argued that only those who meet certain minimal standards should be granted the master's degree in economics. Perhaps other degrees should be used for those who want and deserve a master's but who do not meet the requirements for the master's degree in economics. But the degree

[17] Cf. New England Conference on Graduate Education, *Report of Subcommittee on Requirements for Master's Degree,* 1946.

in economics should be maintained as signifying a certain level of ability and certain achievements *in economics*.

Those who do not meet these standards may have excellent reasons for pursuing their particular studies, but they should not be awarded the master's degree in economics. Thus, if a prospective secondary teacher wishes to devote much of his time to the study of educational methods, or to the study of a variety of social sciences, without mastering the minimal requirements in economics, this may be entirely defensible, but it should lead to a degree in "education" or in "teaching of the social studies"—not in economics.[18] If an individual wishes to enter a program of study pertaining directly to security analysis or to statistical methods in sales forecasting or to some other aspect of a job, without meeting the requirements in economics, perhaps he should be permitted to do so, but he should not be awarded the master's degree in economics. Similarly, if a student wishes to round out his education with a fifth year of liberal education, without meeting the requirements in economics, he should be permitted to do so—but again without the expectation of receiving a master's degree in economics.

Nevertheless it can be argued that many students in each of these three groups would be wise to meet the requirements in economics rather than merely to pursue narrow vocational interests or to become dilettantes. My conversations with educators suggest that the profession of teaching social studies in secondary schools would be enriched if it included more persons who have substantial training in economics. At present, most teachers of the social studies are, quite properly, trained in history. Many believe, however, that it would be desirable if a somewhat larger number of these teachers were well-trained in economics (or in sociology or political science). Those who wish to pursue some specialized vocational training are often deluded into thinking that the only education they need is that which is directly germane to the particular job on which their attention is fixed. They sometimes forget that versatility and ability to develop come through laying a foundation on which many different kinds of skills can be based rather than through acquiring one specialized skill that is not easily transferable. If one wishes to be a forecaster of sales, it is better in the long run for him to know about the fundamentals of statistics and economics than to know the latest techniques for gauging next month's sales of toothpaste. Likewise, many of those who wish merely

[18] Cf. Roger P. McCutcheon, "The Master's Degree and the Teacher Requirements," *School and Society*, Sept. 22, 1951; and Committee on Graduate Work, Association of American Universities, "The Master's Degree." *Journal of Proceedings and Addresses*, 1945, p. 14.

to add a fifth year of general education may be well-advised to buckle down to a basic regimen in economics or some other solid field rather than to pick up scattered and unrelated samples of superficial knowledge. All of this argues for a solid program in economics leading to the master's degree for many students in the first three of the six groups listed above. And all students in the last three groups, it may be presumed, should be interested in such a basic program in economics. These include the prospective college teachers, the prospective economists in business and government, and those planning to go on to the Ph.D.

The conclusions, then, are (a) that only those students who measure up to the requirements for a master's degree *in economics* should receive this degree, and (b) that most students who are interested in some aspect of economic study probably would do well to try to meet these requirements. Apparently, a large majority of the profession agrees with this position. Only 4 of 50 reporting departments indicated that they attempted to offer separate programs for some of the several classes of students. In a questionnaire directed to graduate professors of economics, I asked if they felt that the diversity of career objectives among first-year students was a serious handicap to the instructional program. More than two-thirds answered in the negative, and only about 7 per cent gave an unqualifiedly affirmative response. I also asked if they felt that the several types of students should be distinguished and distinct programs arranged for some or all of the groups. More than half answered in the negative and only about 10 per cent were definitely favorable. Of those who answered negatively more than half indicated that the same type of program would be suitable for most or all students, and that minor variations in student needs could be easily handled on an individual basis. Others felt that the number of students does not justify several programs, that many students are too uncertain regarding their future plans to warrant further specialization, or that the creation of several programs would lead to undesirable specialization. I feel that all of these are cogent arguments. My conclusion is unequivocally that there should be one basic program and one degree for first-year graduate students in economics regardless of their ostensible career objectives, that this program should be flexible enough to take care of variations in individual backgrounds and needs, and that it should be rigid enough to insure that everyone who receives a master's degree in economics meets the standards which that degree should symbolize.

Regarding those students who are planning to proceed to the Ph.D., the issue is frequently raised as to whether they should actually take the master's degree on the way to the Ph.D. Only 7 of 36 reporting

universities ordinarily required the master's degree of students who are to become candidates for the Ph.D. About half recommend that the student take the master's degree en route to the Ph.D. A few universities are discouraging prospective doctoral students from taking the master's degree or at least are not requiring or encouraging them to do so.

In some universities, the master's degree is granted automatically to students who pass the preliminary examination for the Ph.D., and also to those who fail to pass the preliminary examination but who are nevertheless judged worthy of the master's degree. In others, the master's degree is ordinarily granted only to those who fail in the preliminary examination, and the degree thus becomes a kind of "consolation prize." In these institutions, those who pass the preliminary proceed directly to the doctorate without taking the master's degree at all. In either case, there are no special requirements or formalities for the master's degree. If the degree is granted, it is done merely as a perfunctory gesture or as a consolation prize.

This tendency to eliminate the master's degree as one of the steps to the doctorate is, in my judgment, a serious mistake.[19] It is a practice likely to result not only in further depreciation of the master's degree but ultimately in a deterioration of standards for the doctorate as well.

There are several reasons for this conclusion. First, the procedure by which the master's candidate prepares a thesis and submits to formal comprehensive examinations provides an excellent device for determining his fitness to proceed to the doctorate. A faculty advisor and an examining committee for a master's candidate are in a strong position to handle the difficult problem of eliminating unfit students. They can pass simultaneously on qualifications for the master's degree and fitness for further study toward the Ph.D. At this point the better students can be systematically encouraged and the unqualified weeded out. Second, the requirement of a valid master's degree in economics provides the leverage by which the student may be required to make up deficiencies early in his graduate career. By denying the master's degree until first things have been done, the student is forced to build a secure foundation for his later doctoral studies. Third, the necessity of meeting the requirements for the master's degree provides the student with an immediate and specific goal for his early graduate work. This helps to

[19] Cf., Committee on Professional Training, American Chemical Society, "Philosophy of Graduate Training at the Ph.D. Level," *Chemical and Engineering News*, Jan. 19, 1948. This report states (p. 167) "The master's degree should not be used as 'consolation' to a doctoral candidate who has proved to be unsatisfactory, but should be awarded only on its own merit to students who have demonstrated positive achievement well beyond the bachelor's level."

give focus to his early work and offers strong incentives to accomplishment. Fourth, the writing of a master's thesis is first-rate experience for the younger graduate student. Fifth, the requirement of a sound master's program in the early years would tend to insure a well-rounded education for those who are forced to drop out before completing their course work for the doctorate. Fewer would end up with incomplete or fragmentary programs. Finally, if these same students who were forced to drop out—many of them for reasons unrelated to their competence—were awarded a master's degree, they would be able to go forth with a definite and widely recognized symbol of their achievement.[20]

My conclusion, then, is that the great majority of students in the first year of graduate study should enter a basic, non-specialized program of study in economics and that this program should lead to the award of the master's degree to those completing it successfully. Those who do not see fit to enter such a program—even for the best of reasons—may well be permitted to pursue their studies and may well be granted degrees of some kind but they should emphatically not be awarded the master's degree in economics. That degree should be reinstated as one signifying a substantial accomplishment in economics and a level of professional competence as an economist.

If the objective of revaluating the master's degree is to be achieved, one practice all too common in American universities must be discontinued. This is the practice of granting the master's degree after one year's graduate work—after the accumulation of so many hour's credit—almost regardless of the student's prior achievements or his general "mastery" of the field. As one professor puts it: "Our master's program accepts the student as he emerges from undergraduate school and takes him as far as he can go in one year." The master's degree should be awarded on the basis of standards of achievement, not on the basis of clock hours devoted primarily to repairing deficiencies in the student's background.[21]

[20] Many but not all graduate professors agree with the position that the master's degree ought ordinarily be taken on the way to the Ph.D. When queried on this point 27 out of 59 graduate professors were in favor, 16 thought it depends on the individual student and his needs, 10 thought that the taking of a master's doesn't make much difference, and 6 were opposed. One of my critics who agrees with my general position said, "While, in general, doing the master's degree is a good thing, I find occasional very good students who understand researching, organizing, and writing up materials and who therefore make better use of their time if they do not take the master's." I do not disagree with this but I believe (as does my critic) that there are relatively few such students.

[21] Cf., Committee on Graduate Work, Association of American Universities "The Master's Degree," *Journal of Proceedings and Addresses*, 1945, p. 6. This report states (p. 9): "This degree should represent successful completion of an educational experience one stage beyond the Bachelor's degree both in specialization and in the character of the subject-matter

Having argued for the reinstatement and revaluation of the master's degree in economics, the question remains: What should be the minimal standards by which master's candidates should be judged? In general, the criteria would be similar to those for the doctorate except that standards would represent a generally lower order of ability and achievement.

1. *Personal qualities.*
   (a) In general "intelligence," a master's candidate should rank at least among the top third of all college graduates—as measured by his undergraduate grades or his achievement on appropriate tests.[22]
   (b) He should have the motivation, initiative, and energy for further professional growth, though not necessarily at the rate required of a Ph.D. candidate.
   (c) He should have the emotional stability necessary to function in the kinds of positions economists are called on to fill.
   (d) He should be a person of integrity and good character.
2. *Knowledge.*
   (a) *Common Core.* He should have a knowledge of economic theory equivalent to that which could be obtained in rigorous one-year graduate courses for which undergraduate intermediate theory and money and banking is a prerequisite. His knowledge of theory should include value, distribution, money and employment. He should have a knowledge of statistics such as could be acquired in a solid half-year graduate course for which an elementary undergraduate course is a prerequisite. It is possible that economic history and history of economic thought would not be included in the core for the master's candidate, though of course they would be highly recommended.
   (b) *Special fields in economics.* Each candidate for a master's degree should be prepared in one or two special fields in addition to the common core. If one field is offered, his preparation should be the equivalent of what could be obtained in a

studied and the manner of presentation. An ideal requirement for the attainment of this degree is the kind of intellectual development and demonstrated performance that could be expected from a student who has had broad and thorough undergraduate preparation for his subsequent work, has manifested scholarly interests by his undergraduate record or otherwise, and has zealously devoted himself for at least one year to work as a graduate student under the active guidance of able scholars and teachers and with the proper use of adequate library and laboratory facilities, all (or at least a great majority) of the courses pursued being at a level which presupposes knowledge of the elements of the subject-matter studied."

[22] Cf., "The Master's Degree," *op. cit.*, p. 13.

one-year graduate course. If two fields are presented, his preparation in each should be equivalent to what could be obtained in a half-year graduate course. In case a student wished to present a field from the common core as a special field, he would be permitted to do this by presenting evidence of mastery beyond that required for all students. All students should write a master's thesis or equivalent in the major field.

(c) *General knowledge of the entire field of economics.* A master's candidate cannot be expected to have the breadth of knowledge required of a candidate for the Ph.D. However, he should have a knowledge of perhaps three fields, in addition to his common core and special fields, equivalent to that which could be obtained by taking any undergraduate "survey" course in the field or reading an elementary textbook.

(d) *Research tools.* The master's candidate should not be required to show proficiency in any research tools (except statistics which is covered under the common core).

(e) *Fields outside economics.* The master's candidate should not be expected to show the breadth of knowledge required of the Ph.D. However, he has presumably completed a liberal education and should be held for a range of knowledge such as a graduate of a liberal arts college, placed in the upper third of his class, could reasonably be expected to have, plus that which an intellectually curious and alert person would have acquired independently. He should be specifically required to repair gross defects in his general intellectual background before he is awarded a master's degree.

3. *Abilities and skills.*

(a) *Reading.* A candidate for the master's degree in economics should be able to read with comprehension any of the easier professional literature in the common core and in his special fields and he should be able to understand its relevance to problems and issues.

(b) *Writing.* He should be able to write correctly and with logical organization, brief or fairly extended discourses on subjects in his special fields.

(c) *Speaking.* He should be able to present an economic subject before a class or small group, and to explain a point in an informal discussion. The requirement in speaking should be thought of jointly with the requirement for writing and high competence in one should substitute for deficiency in the other.

(d) *Teaching.* Under supervision, and with time for preparation, he should be able to teach the first undergraduate course in principles of economics.

(e) *Research.* He should be able to carry on limited research projects under general supervision, or to serve as a useful research assistant under the detailed supervision of a mature research worker. He should be able to use economic theory to a modest degree in analyzing the effects of changes in economic variables and in formulating research hypotheses.

(f) *Writing for publication.* The master's candidate should not be required to be able to produce manuscript that is at a level of quality acceptable for publication. He should, however, be able to write acceptable memoranda and reports. The writing of a thesis should be both preparation to meet this requirement and a test of the student's ability to meet it.

4. *Professional orientation and motivation.*

(a) The candidate for the master's degree should exhibit a serious interest in economics, and a desire to continue his study of the field.

(b) He should have achieved a degree of objectivity and critical facility in matters relating to economics, and a respect for logic and evidence.

5. *Capacity for growth and adaptation.* The candidate for the master's degree should have the motivational pattern and the intellectual equipment necessary for professional growth and for adaptation to new developments in the field. A person who has completed the requirements for the master's degree but shows no ability or inclination to grow or to carry on further work in the field should probably not be awarded the degree.

I believe that these standards are in accord with much of the thinking of graduate professors of economics although they apparently seldom consider standards or educational objectives explicitly in terms of what the student can *do* as distinct from what he *knows*. When a group of graduate professors were queried on their conception of the "knowledge, abilities, and personal qualities" which a master's degree in economics should symbolize, they provided a variety of responses. Many of them emphasized analytical ability, facility in the use of theory, and a grasp of "economic relationships." Some stressed the ability to read economic literature, to write, and to teach. Others thought that knowledge of sources of data, of research techniques, and of practical ability to do research work under supervision are of prime importance. A few mentioned knowledge of current policy issues,

awareness of "intellectual issues," knowledge of economic history and institutions, objectivity, maturity, curiosity, etc.

My discussion of the master's degree in economics has been predicated on the assumption that it should become a significant degree representing substantial achievement and ability; that most graduate students in economics should be candidates for this degree in the early portion of their graduate study; and that among the students who should take the degree are those who are planning to work toward the Ph.D. To adopt the conception of the master's degree here outlined would require a substantial raising of standards and tightening of requirements in many universities. I believe that the result would be a desirable raising of the level of competence in the profession generally even if it should result in a reduction in the number of students receiving degrees.

Experience in the universities which are attempting to maintain standards for the master's degree at about the level suggested here indicates that more than one academic year is usually required for the completion of the master's degree. Apparently, only the most unusual and well-prepared students finish in one academic year. Most students require from a summer session to a year of additional time. Students with assistantships often take 2 full years.[23]

Attitudes Toward Present Standards

To learn something about the extent of satisfaction with present standards for the master's degree and the Ph.D. I asked graduate professors of economics this question:

> What percentage of the students whom you are turning out with master's degrees or Ph.D.'s in economics have, in your opinion, a knowledge of the field of economics and an ability to use this knowledge that is commensurate with your concept of what a master's degree or a doctorate in economics should signify?

The responses were as follows:

	Master's Degree[24]	PhD.[25]
Half or less	13%	20%
More than half; less than three-quarters	10	5
Three-quarters	13	9
More than three quarters; less than 95 percent	39	27
95 percent or more	7	5
No answer	18	34
Total	100	100

[23] Cf., Association of American Universities, "Report of the Committee on Graduate Work," *Journal of Proceedings and Addresses*, 1945, p. 6.

[24] Schedule IV: 61 respondents.

[25] Schedule VII: 59 respondents.

Those who felt that a significant number of degrees are awarded to persons who do not measure up explained the failure in several ways. Some thought it was due to inadequate prior preparation of students, lax admission standards, or inadequate attention to the weeding out of unfit students. Others attributed it to failure on the part of the faculty to define standards and to apply them faithfully once defined. Others said it was a policy to use the master's degree as the device for gently easing out students who are unqualified to proceed to the doctorate. And some thought the trouble lay in the shortcomings of faculties or of facilities for the proper training of students. In general, the blame was usually placed on the faculty in one way or another.

Apparently many of the respondent professors felt that present standards are somewhat ambiguous or in need of careful formulation, since a majority expressed themselves affirmatively on this question:

Do you believe that a useful purpose would be served if the American Economic Association or some other qualified agency were to define minimal standards for the master's degree and the Ph.D. in economics?

The replies to this question were:

	Master's degree[26]	Ph.D.[27]
Yes	51%	32%
Yes, qualified	23	24
Uncertain	8	12
No	13	24
No answer	5	8
	100	100

[26] Schedule IV: 61 respondents.

[27] Schedule VII: 59 respondents.

Chapter 5

RELATIVE QUALITY OF GRADUATE STUDENTS IN ECONOMICS

Economists everywhere are interested in the question of whether the graduate students attracted into the field are of a quality superior or inferior to those who enter other fields of graduate education and other learned professions. Evidence on this subject is difficult to obtain, and such evidence as is available cannot easily be appraised. Fortunately, additional data on this subject are being collected by the Commission on Human Resources and Advanced Training under the direction of Dr. Dael Wolfle. But from this important and ambitious study only certain preliminary results are available as I write.

Evidence from Graduate Record Examinations

The most comprehensive data on the relative quality of graduate students in various fields are provided by the results from the Graduate Record Examinations. These tests, devised to aid in appraising candidates for admission to graduate school, have been given since 1937 to many thousand prospective and enrolled graduate students. The tests were originally developed as a research project of the Carnegie Foundation for the Advancement of Teaching and are now administered by the Educational Testing Service of Princeton, N.J.

In 1947 a comprehensive report was published comparing the scores of graduate students in various fields who had been accepted for admission during the years 1945-47.[1] To avoid biased samples, only those students were included who were in graduate schools requiring the examination of all members of a class. This restricted the data to 41 graduate schools and 5,972 students. Comparative data by major fields were made available for the 24 fields which were represented by 50 or more students.

The tests for which comparative data are available are the profile tests in eight parts: mathematics, physics, chemistry, biology, social studies, literature, fine arts, and verbal factor. The results of the tests are in the form of a set of scores on each of the eight parts. The scores are expressed on the basis of scales in which 500 is the average score of the original standardization group (a highly selected sample of pre-war male students in universities of Northeastern United States) and

[1] The Graduate Record Office, *The Performance of Accepted Graduate Students on the Profile Tests, 1945-1947,* New York, 1947.

TABLE 12.—GRADUATE RECORD EXAMINATION PROFILE TESTS: MEAN OF SCALED SCORES BY MAJOR FIELD OF STUDENTS TESTED[a]

Major field of students tested	Subject of tests								
	Mathematics	Physics	Chemistry	Biology	Social studies	Literature	Fine arts	Verbal factor	Number tested
All fields combined	436	449	447	449	382	408	422	403	5,972
Biology	420	455	495	554	343	394	409	405	86
Zoology	441	487	497	591	354	387	432	413	74
Chemistry	524	557	597	510	379	395	418	407	455
Biochemistry	500	534	582	546	353	383	421	402	55
Mathematics	578	516	478	442	383	412	406	421	129

[a] Graduate Record Office, *The Performance of Accepted Graduate Students on the Profile Tests*, 1945–47, New York, December 1947, pp. 16–27.

the standard deviation is 100. Table 12 presents the mean scores for each part of the test for students who were majors in various fields including economics.

These data indicate that the profiles of the scores for students of various fields differ significantly. Those in the natural sciences tend to have higher scores in mathematics and natural science and lower scores in the social studies and humanities; students of the social studies have relatively higher scores in the social studies and the humanities, and lower scores in the natural sciences; etc. Economists apparently tend to have fairly horizontal profiles. Their performance on each part of the test is not far from that for the average of all students except in the social studies portion where it is significantly higher.

Among the 24 student groups included in table 12, the rank of students of economics in the various parts of the test were as follows:

Mathematics	8th
Physics	13th
Chemistry	14th
Biology	16th
Social Studies	4th
Literature	10th
Fine Arts	13th
Verbal factor	5th

From these results one gains the distinct impression that students admitted to graduate study in economics are near the average of students in all other fields. In no field are the scores of economics students markedly lower than those for all students combined.[2] Their scores tend to be relatively low in the natural sciences and relatively high in mathematics, social studies, and verbal factor. The fact that they are relatively high on the verbal factor portion is significant because this possibly measures general "intelligence" more adequately than any other part of the test.

Evidence from Other Tests

The commission on Human Resources and Advanced Training has collected and summarized a mass of data on mean intelligence scores of undergraduate and graduate students by major fields.[3] Some of these data, as summarized by the Commission, are presented in tables 13 and 14. The data are converted to a common scale in which the mean for the general adult population is 100 and the standard deviation is 20.

Five scores are given for each field, one each for the 10th, 25th, 50th, 75th, and 90th percentile. In interpreting these scores, one should visualize that the students in each group are arrayed, with respect to their scores from the lowest to the highest. The scores for the 10th percentile would then be the score of the person at the top of the lowest ten percent, the score for the 25th percentile would be the score of the person at the top of the lowest 25 percent, etc. For a single comparison of the fields, the 50th percentile, or the median, would be most useful, but the other percentile scores would reveal the distribution of scores.

As tables 13 and 14 show, the scores for students of economics are very near those for "all fields combined." According to these data, students of chemistry, other physical sciences, and psychology show

[2] The Graduate Record Examinations are strongly weighted toward the natural sciences in that three parts are devoted to physics, chemistry and biology; whereas, only one part is devoted to the social studies. This tends to make the profiles appear more favorable to the students of natural science—especially physicists and chemists—than to the social science students.

Physical education	99	110	117	124	134

[a] Wolfle and Oxtoby, *op. cit.*, p. 2. The sample includes about 10,000 students.

relatively high scores; and students of physical education and home economics rank relatively low. It is noteworthy, also, that students of business stand several points below students of economics.

Still further information on the relative test scores of graduate students in economics, as compared with those of other fields, is derived from results of tests administered in 1950-51 in a leading university to students entering graduate study. These results are confidential and cannot be published except in summary form. On a scale in which the average of all graduate students at that university was 500, the mean scores for 28 economics students on the several tests given in 1950 were 482, 507, 445, 465, and 494; and the scores for 29 students on tests given in 1951 were 483, 482, 481 and 490. On the tests given in 1950 economics students as a group, out of 24 fields, ranked

from 12th to 19th on the various tests. On the tests given in 1951, with 17 fields reported, the economics group ranked from 9th to 15th. At this university, graduate students in economics are evidently below the average of all graduate students.

Dr. Elbridge Sibley, in his study *The Recruitment Selection and Training of Social Scientists,*[4] compiled data on the relative standing in their classes, as measured by grades, of undergraduate students majoring in various disciplines at five colleges. He classified the stu-

dents into three groups: (1) "outstanding," those in the top 7½ percent of students; (2) "superior," those in the next 26½ percent of students; and (3) "mediocre and inferior," all others. The percentage distributions of students in each of several disciplines are shown in table 15. The percentage of outstanding and superior students in the natural sciences and humanities exceeded that in the social sciences. In economics, the percentage of outsanding and superior students was slightly less than that for the social sciences in general and for all fields. The percentage of outstanding and superior students was conspicuously less for business administration than for economics. As Dr. Sibley was careful to point out, grades are not an infallible measure of the relative quality of students, especially when comparisons among students in different disciplines are being made. However, he obtained consistent results with a group of students in the two-year college of

the university of Chicago, all of whom took substantially identical work in college but later majored in different fields.[5]

In connection with the Graduate Record Examination, data have been compiled on the mean scores earned by college seniors on tests of general education.[6] Out of 31 major fields, the students of economics ranked, in the various parts of the examination, as follows:

General Mathematics	9th
Physical Science	13th
Biological Science	21st
Social Studies	3rd
Literature	17th
Arts	22nd
Effectiveness of Expression	16th
Vocabulary	16th
General Index	17th

From the results of examinations for Junior Professional Assistants, the U. S. Civil Service Commission has compiled the comparative scores of those designating economics as their option and those designating other fields. The median scores for the group taking the examination in December 1951 were as follows:[7]

	Verbal ability test	Quantitative ability test	Abstract reasoning test
economists	40	21	35
bacteriologists	38	19	35
geographers	38	20	34
geophysicists	41	26	39
social science analysts	42	20	35
statisticians	41	23	38

On a similar examination given in 1941, data on the percentage of persons passing the general test were as follows:

economists	84%
administrative technicians	87
chemists	80
geologists	80
meteorologists	84

Relative Ability of All Graduate Students

In comparing graduate students of economics with those of other fields, it must be remembered that graduate students as a whole are a

[5] Sibley, *op. cit.*, p. 26-27.

[6] These data are available in mimeographed form from the Educational Testing Service, Princeton, N.J.

[7] These data were kindly supplied by Mrs. F. W. Luikart, Chief of the Examining and Placement Division.

highly selected group. To say that economics students are near the average of all graduate students, is not to say that they are second-rate; the total population of graduate students with whom they are being compared is composed of a highly-gifted group. Dr. Wolfle and Dr. Oxtoby have shown,[8] that only about 10 percent of the total population of this country earns test scores higher than the average for all college graduates, only about 7 percent of the total population earns scores higher than the average for all graduate students; and only about 2 percent earn scores higher than the average of Ph.D.'s in the natural sciences.[9]

To show the relative order of ability of all graduate students, Dr. Sibley compiled data on the graduates of the five colleges included in his study, by occupation or field of graduate study. As shown in table 16 the college graduates who attend graduate schools of arts and sciences include a high percentage of outstanding and superior students as compared with those who do not enter graduate study of any kind, and also as compared with those who enter the study of business administration, law, and medicine.

A related study of graduates of the High School of the University of Minnesota who have taken advanced degrees confirms Dr. Sibley's results. The mean intelligence quotients of this group, by type of advanced degree, are as follows:[10]

D.D.S.	112
M.D.	123
LL.B.	127
Master's	127
Ph.D.	132

The fact that graduate students rank about as high as medical students (in some studies higher) is of special interest because of the extreme care with which the latter are reputedly selected. Available evidence indicates that in terms of college grades and scores on tests, medical students are not necessarily more gifted, as a group, than students in graduate schools or arts and sciences. See tables 12, 14, and 16.

Concluding Comments

Certain very general and tentative conclusions can be drawn from available data on the quality of students who enter graduate work in

[8] *Op. cit.*, p. 1. Cf., data on distribution of Army General Classification Scores by highest year of school completed, President's Commission on Higher Education, *Higher Education for American Democracy*, Washington, 1947, Vol. 6, p. 11.

economics. First, graduate students in economics are apparently well-rounded; i.e., they have relatively equal abilities on the various portions of tests. They are apparently neither outstandingly deficient nor proficient in any field of learning. This is revealed by the horizontal form of the profiles of economics students as compared with those in other fields (see table 12). Second, economics graduate students tend to be near the average for all graduate students (see tables 12, 14, and 15).

Of interest because of the close relation of economics to the field of business, is that students of business administration apparently make somewhat poorer showings on the various scores than students of economics (see tables 12, 13, 14, 15, and 16).

Any conclusions drawn from the data presented must be interpreted with caution. First, the samples from which the data are drawn are limited. Second, it is possible that some of the tests may be designed in such a way that students with particular talents or training will be able to make better scores than others. Differences in the scores might then not reflect differences in basic ability or intelligence. Third,

the ability to make high scores on intelligence tests or high grades is not the only criterion of the quality of students. Indeed, studies of the relation between test scores or undergraduate grades and "success" in graduate schools seldom yield correlation coefficients above 60 or 70. While this is considered high for this type of correlation, yet it suggests the presence of important factors in graduate school success other than ability to make high scores on tests or a good undergraduate record. Fourth, the attractiveness of various fields to bright students may change according to the times. It is possible, though I have no evidence, that economics had greater attractiveness to good students in the 1930's than it has today; and that today the physical sciences may be relatively more attractive as a result of enormous publicity.

It is easy to find arguments for questioning or ignoring test scores and undergraduate grades as a measure of the relative quality of students in various fields. Yet, the general consistency of the data from several sources indicates that these results cannot be lightly dismissed.

Members of the economic profession can take some satisfaction from the fact that the new recruits into the profession are in ability near the average for all graduate students. This is near the average of a very select company. They can also be pleased that there are many new recruits who are far above average. However, they should not become complacent on the basis of the average or near-average ability of the new recriuts.

The average for all students includes fields such as fine arts, music, physical education, education, dentistry, home economics, and social work—fields which do not ordinarily draw the cream of graduate students or which do not require high proficiency in academic subjects. Among the more traditional academic fields, economics is well below average.

The profession would do well to proceed on the assumption that the average ability of students attracted into economics is lower than it should be in relation to the intellectual demands of the field and its importance in our national life.

Chapter 6

RECRUITMENT AND SELECTION

The usual avenue by which young men and women enter the profession of economics is graduate study. The procedures in the recruitment and selection of persons who are to study economics at the graduate level is, therefore, a major factor determining the quality of future personnel in the field. I believe that the profession is not fully meeting its responsibilities in recruitment, and selection.

Evidence from professors and from employers of economists indicates that for many years there has been a ready market at prevailing salaries for persons with graduate work in economics. But there is no critical shortage of economists in the same sense that there is said to be a shortage of engineers or physicists. Current quantitative demands for economists hardly justify an intensive campaign to recruit people into the field, and do not warrant sacrifices of quality in the interests of quantity.

The evidence of the preceding chapter suggests that the profession might wish to recruit more students of high quality and to reject some of the less capable ones now being admitted.[1] This raises the interesting question of how students now find their way into economics.

Decisions to Enter Graduate Study in Economics

As shown in table 17 the present and former graduate students responding to my questionnaires first decided to major in economics at widely varying times. Less than 10 percent had decided before entering college, about 40 percent had decided by the end of the second year of college, and only about three-fourths had decided by the end of their college careers. The time of decision to undertake *graduate* study in economics was still later. Only about a third had made up their minds prior to the fourth year of college, and only a little more than

[1] Apparently many graduate professors agree with this position. Most departments report that they are trying, through scholarships, personal advice, and assisting students to get scholarships elsewhere, to encourage good students to enter graduate work in economics. And most of them feel that greater efforts should be made to stimulate the flow of *good* students into the field. Many of them emphasize that it is more *good* students—not just more students—that is wanted. On the question of supply of personnel into economics, one of my critics writes: "One of our problems is to learn to use lesser talent more successfully than we do. I have the feeling the laboratory sciences do a better job of this than does economics. I believe, in any case, that we should treat talent as a scarce resource to be used as all other resources and we should try to meet the lack largely by having our society provide more in general rather than by pulling it from other fields."

TABLE 17.—TIME OF DECIDING TO MAJOR IN ECONOMICS AND DECIDING TO UNDERTAKE GRADUATE STUDY, GRADUATE STUDENTS AND FORMER GRADUATE STUDENTS[a]

	Decision to major in economics	Decision to undertake graduate study[b]
Before entering college	10%	12%
During first two years of college	32	9
During third year	21	13

say they chose economics as a major (Table 18) because they became interested in the field, presumably from experiences prior to college or from courses taken in college. The advice of relatives and professors and the desire for careers in the field were apparently secondary influences. It is notable that the number mentioning direct influence of professors was few as compared with the number mentioning interest in the subject.

Among the influences underlying the decision to enter graduate study (Table 19), interest in the subject is important, but more than half mentioned the desire to seek a career in teaching or other professional work as a primary motive.

Recommendations on Recruitment

Since the decisions to take up economics as a major field of study and to enter graduate school are ordinarily made—and should be made

—during the student's undergraduate years, the practical things that can be done to attract a larger number of capable students into the field are things that must be done in the undergraduate colleges.

The first of these, of course, is to interest more *good* students in majoring in economics. This is largely a matter of the quality of teaching and of text materials in the first courses. In institutions where the teaching of principles of economics is regarded as a hack job to be done by assistants, the prospect of kindling real interest is, of course, very slight. But this opens up a big question that exceeds the bounds of the present study.

A second, and much simpler suggestion, is to help undergraduate students to realize that there *is* a profession of economics, that it offers wide and varied opportunities, and that it is by no means a strictly

academic field like classical languages or medieval history. Young people often have direct acquaintance with law, medicine, dentistry, business, agriculture, engineering, and education. Fields like chemistry and physics are well known to them by reputation if not by actual contact. But they are unlikely to have known an economist or to have had the vaguest notion of what he does or of what opportunities are open to him. It would seem useful, then, for departments of economics to provide systematically some professional orientation for their undergraduate students.[2]

In my discussions with teachers of economics, I have found that many are themselves lacking in an understanding of the professional opportunities available to economists. Several have asked me: "What do you tell a student when he inquires about vocational possibilities in economics?" The answer is to be found, for example, in the admirable statement prepared by a Committee of the American Economic Association,[3] or perhaps in the first chapter of this study. It is obvious that economics is a growing and expanding field and that there are many socially useful, interesting, and reasonably remunerative careers for persons trained as economists. These facts should be brought to the attention of students—even in the first course. To do so would be not solely an act of proselyting but a proper educational task. It may be as important for students to know what an economist is and what he does in our society as to know about Gresham's Law or the kinked demand curve.[4] It is particularly important to acquaint students with these matters early, because the sooner the decision to become an economist is made, the more adequate can be the preparation for graduate study.[5]

Third, special attention should be given to counselling with superior students who have elected economics as an *undergraduate* major. This is not to suggest that all such students should be urged to undertake graduate study,[6] but only that the opportunities in professional

[2] Some departments do try to acquaint students with the possibilities of and the requirements for graduate work in economics, but I have the impression that much of this is very casual.

[3] "The Profession of Economist," *American Economic Review* (supplement), Jan. 1949, pp. 341-43.

[4] Sibley (*op. cit.*, p. 22) points out that the social sciences, unlike the natural sciences, give the undergraduate student no notion of what scholarly work in the field is like. Therefore, students have little chance of learning about the professional possibilities in the field and teachers have little opportunity to identify the students who ought to be encouraged to go on.

[5] Cf. Commission on Human Resources and Advanced Training, *Plans for Studies of America's Trained Talent,* Washington, 1951, p. 11.

[6] Cf. Horace Taylor (editor), "The Teaching of Undergraduate Economics," *American Economic Review* (supplement), Dec. 1950, pp. 139, 151.

economics should be pointed out to them as one promising option. Seminars for superior undergraduate students may be useful in acquainting them with what economists do.

Fourth, graduate departments of economics should have more scholarships for first-year graduate students to be used to attract the most promising students. In many institutions a large part of student aid is in the form of assistantships to second-year and third-year graduate students. It is desirable, of course, to give financial aid in the later years, but for recruitment of outstanding students, it is crucial to give such aid in the first year. If the student is not able to begin graduate work, he can never complete it. Moreover, in administering aid to graduate students, departments should take care that brilliant first-year students are not denied well-deserved aid while funds are used to support indifferent graduate students who have earned only seniority.

Fifth, graduate departments might well maintain close liaison with smaller liberal arts colleges and municipal colleges with a view to discovering and encouraging the more gifted economics majors who might undertake graduate work. This is being done systematically by the graduate colleges of several southern universities under grants from the General Education Board. With declining graduate enrollments, rivalry for *known* students of high ability has become unusually keen. But this is competition for students who have already decided to undertake graduate study and have made application for scholarships. Few universities have attempted to discover *unknown* talent. That is what I am suggesting. It should be worth at least as much time, trouble, and money for an economics department to discover a gifted economist as for a football coach to find a star halfback.[7]

Interesting and promising new schemes for the recruitment of graduate students in the social studies are the Woodrow Wilson Fellowships sponsored by the Association of Graduate Schools of the American Association of Universities, and the Undergraduate Research Stipends of the Social Science Research Council. The theory underlying both of these programs is to seek out superior young people and to encourage them to enter graduate work.

[7] See T. R. McConnell and L. A. Lovegren, *A Study of Assistants at the University of Minnesota* (mimeographed), Minneapolis, 1937. This study reported the tendency of departments at the University of Minnesota to grant financial aid to students who have done previous work at that institution, and (p. 11) to the "general lack of aggressiveness in recruiting promising graduate material." The study reported that ten of thirty-three department heads interviewed made an active search beyond the institution for outstanding assistantship applicants.

Admission

After recruitment, perhaps the most important factor determining the quality of professional personnel in economics is admission to graduate study.

The most general requirement for admission to graduate study in economics is a bachelor's degree, though a few universities permit some seniors to enroll in graduate courses prior to the completion of undergraduate requirements. Most graduate departments of economics also require a minimal grade average in undergraduate work. These grade requirement in 84 departments for which data are available are as follows:

Honors	4
B plus	4
B	33
B minus or C plus	15
Upper half of graduating class	4
C	3
No requirement	7
Other	2

Practice varies considerably regarding the specific substantive content required of applicants. Out of 84 departments for which data were obtained, 39 require that the applicant have completed an undergraduate major in economics (usually as the major is defined at the institution of application), 31 require "substantial background in economics or social science," 30 require a course in statistics, and 6 have no substantive requirements in economics. In the "tool" subjects, 13 departments require accounting, 8 require mathematics, and 8 require one foreign language. A few institutions require courses in fields other than economics or "tool" subjects related to economics; among these requirements are political science, sociology, history, commerce, finance, and laboratory science.

All except one of the institutions reporting indicated that there are provisions for students to repair deficiencies in their backgrounds while enrolled as graduate students. The provisions include enrollment in undergraduate courses without credit (19 out of 67 reporting institutions), requirement of additional courses (42), passing special examinations (3), and enrollment as a special student (2).

Entrance examinations as a condition of admission are given by only a few institution—8 out of 54 reporting. Among the examinations given are the Miller Analogies Test, certain of the Graduate Record Examinations, the G.E.D. social studies test, and a reading and com-

prehension test. In only 5 institutions, however, were the scores on these tests used as an important basis for deciding whether or not to admit individual students. Interviews are used when practicable in 31 out of 55 institutions reporting, and letters of recommendation by 30 institutions.

Personal and physical qualities of applicants are ordinarily considered by 10 of 53 institutions and sometimes considered by 5 more. The remaining 40 reported that they gave little or no attention to these qualities in connection with admissions.

About two-thirds of the reporting institutions (35 out of 51) indicated that their admission requirements are administered "strictly and virtually without exception." The remaining third reported that exceptions are made for borderline cases or for students who show unusual promise.

A special admissions problem exists for students who have completed some graduate work and who wish to go beyond the first year in quest of a doctorate. When the first year of work has been taken at the same institution, the problem is one of deciding whether the student should be permitted to go ahead. Out of 34 reporting institutions, 15 indicated that a student who has completed one year of work and has met formal requirements for good standing is automatically permitted to continue. Nineteen institutions stated that there was a screening process at this point—either in connection with the award of the master's degree or otherwise—and that only those students who were judged of doctoral caliber were permitted to go ahead. The problem is also present in the cases of those students who have completed some graduate work and wish to transfer to another institution for study toward the doctorate. Here practice varies enormously and it is difficult to generalize beyond the statement that grades and letters of recommendation are the principal basis of decision in each case. Personal and physical qualifications are considered more frequently in the case of applicants who propose to study for the doctorate than in the case of applicants who are seeking admission to the first year of graduate study.

Opinions Regarding Admission Practices

Apparently there is mild dissatisfaction among graduate professors of economics regarding admissions practices. As shown in table 20, only a minority judged that present procedures and standards are good, most considered them fair, and a sizeable minority thought them poor. On the whole they thought that admissions practices were more efficient in selecting students with adequate intellectual capacity and preparation in economics than in selecting those with adequate preparation in

"tool" subjects or with suitable personal and emotional qualities. Several of them commented, however, that they questioned whether it was a proper function of admissions policy to consider personal and emotional qualities of students. Some made the observation that the personally unsuited eliminate themselves soon after admission.

The respondent professors offered numerous suggestions for improvement in present admissions practices. Many thought that the basic problem is the small number of candidates from which to choose, and that the solution lies in attracting more applicants. Others felt that there is need for obtaining more reliable information on the candidates. They felt that less reliance should be placed on letters of recommendation or that ways should be found to make these letters more revealing. Others recommended that fuller and more accurate information on applicants should be obtained including better means of evaluating student records from smaller colleges. Several thought that personal interviews with students prior to admission should be used more

TABLE 20.—OPINIONS OF GRADUATE PROFESSORS REGARDING PRESENT PRACTICES IN THE ADMISSION OF GRADUATE STUDENTS[a]

Efficiency in selecting students who are adequate with respect to:	Good	Fair	Poor	Un-certain	No answer	Total
Intellectual capacity	27%	50%	17%	3%	3%	100%
Earlier preparation in economics	35	38	14	3	10	100
Earlier preparation in tool subjects	14	31	37	7	11	100
Personal and emotional qualities	19	32	20	20	9	100

[a] Schedules IV and VII: 120 respondents.

extensively. Some recommended that several samples of the applicant's written work should be evaluated. Others said that entrance examinations would be helpful. Many expressed the view that steps should be taken to improve the preparation of students prior to admissions—especially in the tool subjects. They suggested greater publicity regarding the content of desirable preparation for graduate study in economics, the requirement of certain courses in economics and certain proficiencies in the "tool" subjects, entrance examinations, and strict requirements regarding the repair of deficiencies after admission. Many merely suggested stricter standards for admission or more rigorous administration of present stardards. A few pointed out the need for more "ruthless" or "impersonal" attitudes toward applicants.

Admission Policy

On the question of selecting students for admission to graduate work, there are two distinct views. The first is that entrance requirements should be rigid, and selection careful, so that few students will be admitted who will be unable to qualify for the degree normally terminating their course of study. In those institutions which restrict themselves largely to a Ph.D. program, this would mean selecting only those first-year students who may be reasonably expected in due time to qualify for a Ph.D. Similarly, in institutions offering the master's degree, this would mean selecting only those students who are judged capable of proceeding to the master's degree. This view is based on the theory that facilities are limited, and that time and money should be reserved for those students who are able to profit fully from graduate study. As one professor expressed this viewpoint, "Every failure of a student is an indication of a mistaken admission." The second view is that admission standards should be relatively low, but that unqualified students should be weeded out early in the program. This view is based on the theory that it is not possible with present techniques to differentiate sharply between qualified and unqualified students except through actual experience in graduate work, and therefore that a highly restrictive admission policy will deny opportunity to many worthy students. In public institutions, moreover, it is felt that a sharply restrictive policy is likely to have adverse affects on public relations.[8] A third possibility, of course, is to achieve a compromise between these two views by having admission standards that are moderately rigorous. No doubt most actual admission standards lie somewhere between the two extremes.

My own view of the matter is that a middle position is desirable for most institutions. I do not have sufficient faith in available devices for screening candidates to be ready to advocate highly restrictive standards designed to admit no one who would later have to be dropped. The available devices consist of undergraduate grades, tests, interviews, and letters of recommendation. Studies of the prediction of success in graduate school based upon undergraduate grades and tests usually produce coefficients of multiple correlation no better than .60 to .75.[9] Such coefficients may be impressive, considering the nature of the problem and of the data. Yet to rely heavily on undergraduate grades

[8] Apparently graduate professors are about evenly divided on this subject. In response to my questions, 26 of 61 respondents favored a rigorously selective admissions policy, 25 favored a relatively lenient admissions policy with high mortality after admissions, and 10 offered no opinion.

[9] See, for example, G. V. Lannholm and W. B. Schrader, *Predicting Graduate School Success*, Educational Testing Service, Princeton, 1951.

and tests may easily do a great disservice to some of the students who are rejected. Interviews are seldom practicable, and letters of recommendation are notoriously unreliable. Thus, there is apparently no consistently reliable method of screening candidates in advance of admission.

On the other hand, it seems to me foolish to admit students whose academic record, test scores and letters indicate that their chances are negligible of ever being able to qualify for a degree.

The question is where should the line be drawn? The line will, of course, have to be drawn differently at different institutions. Those universities whose prestige or location give them drawing power will be forced to restrict themselves to the number of students they can adequately handle. The only sensible course for them is to try hard to choose the best students from among those who apply. Institutions of lesser drawing power may well offer the opportunity for graduate study to a wide range of students including some of those who may have been rejected by the more restrictive institutions. I believe that a case can be made, in the many institutions which have less than optimal enrollments, for admitting students whose chances of earning indicated degrees are judged to be at least one in two or three. Under this standard, some students who might squeak through to a degree would be rejected, but rarely would a really good student be passed by.

Apparently most institutions are not so crowded with graduate students in economics that this proposal would be impracticable. Only a handful of institutions (approximately 6) actually impose limitations on their enrollments or admissions of graduate students in economics, although a few more would apply such limitations if their enrollment ever reached a specified maximum. And only a small minority of professors (16 out of 120) reported that (in their opinion) there are too many graduate students in their institutions. A much larger number (51 out of 120) thought they had too few students for most effective work. Many felt that with the small numbers now in residence, there was too little competition, too small classes, too little inter-stimulation among students, and too little probability of drawing even a few good students.

The relatively lenient admissions policy I have suggested for all but a few institutions (this is not far from the policy now in effect at many of them) can be defended only if two important conditions are met. First, the weaker students who are admitted must be counselled in advance regarding the odds they are facing so that they will not be misled by the act of admission into false hopes and wasted time.[10] Second, the procedures for eliminating students who, after admission, are found to be unfit must be prompt and efficient.

[10] This can be done only if dependable information is available in advance of admissions.

A lenient admission policy, when these conditions are not met, can only result in sub-standard graduate education. If students of questionable ability are admitted without being warned of the odds they are facing, great courage will be required on the part of faculty members—more than most of them have—to drop such students after their inadequacy has been demonstrated. It is all too easy to let them stay until vested interests are so great that dropping them becomes an injustice. This tendency to retain poor students is strengthened by the desire, in many institutions, to maintain large graduate enrollments, and by the willingness to dispose of poor graduate students simply by granting them the master's degree—a degree which (mistakenly I think) is held in low esteem.

Another danger of a lenient admission policy, when not accompanied by rigorous screening after admission, is that standards will be adversely affected. The presence of students of low quality is a subtle influence toward lowering the standards of a department. The faculty conception of a "good student," an "average student," or a "poor student" is determined partly by the abilities of the students they see and know. The process of judging students consists partly of comparing one student with another, not merely of judging each student by some abstract standard. Therefore, in a department having a large number of students of low quality over a period of years, standards are likely to become lower than in departments which have rigorous policies of selection operating either before or soon after admission.

For all these reasons, my conclusion favoring relatively lenient admission policies in departments which have not exceeded their optimum graduate enrollment is valid only on the assumption that rigorous selection will occur soon after admission. The issue is not whether there should be selection, but only when it should occur and how it should be accomplished.

Substantive Preparation

The discussion of admissions, up to this point, has been concerned primarily with the general intellectual quality of students. Another issue concerns the prior substantive preparation of students who are to be admitted to graduate study. What kind of undergraduate background or prior preparation is desirable or indispensable?

There are two extreme opinions on this issue: One that the background of the undergraduate student is a matter of complete indifference so long as he has had a good liberal education; the other that specific background is important and that the student should not be admitted unless he meets certain definite substantive requirements. The second of the opinions is usually qualified by the assumption that a

student who lacks some of the requirements may be admitted to graduate study on the condition that he make up all deficiences, *in addition* to meeting the normal requirements for his degree. Much opinion lies between these two extremes.

On one point everyone is agreed, namely, that prior preparation is decidedly less important than the basic intellectual qualities of students. Everyone would prefer brilliant applicants with little or no preparation in economics or related fields to dull ones with the most meticulously appropriate backgrounds. But this does not dispose of the question. With students of given abilities, it is surely better to have them appropriately prepared than not. That prior preparation is no trivial matter is indicated by the responses of present and former graduate students. Of 358 respondents, 229 (64 percent) reported that they had been handicapped in their graduate work by inadequacies in their earlier training.

Those so reporting indicated that the following deficiencies constituted handicaps:[11]

Mathematics	41%
Economic theory	21
Statistics	7
Economics generally	25
Social sciences other than economics	12
Foreign languages	8
Literary ability	6
Lack of breadth	5
Faulty undergraduate training generally	14
Other	8

Similarly, few of the graduate professors queried indicated that they regarded substantive admissions requirements as unimportant. Most thought that a major in economics or at least several courses in economics were essential. Many specifically mentioned statistics and economic theory and a few suggested other specific courses. Regarding prior preparation in the "tool" subjects, few favored no requirement, but there was a wide variety of specific suggestions including (in order of frequency): mathematics, accounting, English composition, and logic and scientific method.

I discussed the issue of substantive background with many deans of graduate schools and professors in fields outside economics—in order to learn about the thinking and practices on this issue in other areas. I have found that in other fields—particularly in some of the natural sciences, the undergraduate major is relatively standardized throughout the country. It can be assumed that any person with a major in the

[11] Schedules IX and X: 358 respondents. The total adds to more than 100 percent because some respondents reported more than one deficiency.

field will have had a certain minimal sequence of courses and that the content of these courses will be similar wherever they are taught. In these fields, graduate work customarily presupposes a given undergraduate preparation and builds upon it. Undergraduate economics, on the other hand, is much less conventionalized. Majors in various institutions or even in the same institution may have had widely varied training. There is no generally accepted sequence of courses and no agreed upon content for given courses. This, combined with the fact that more than a third of all economics graduate students have not majored in economics in their undergraduate work,[12] means that those who knock at the door of graduate departments of economics bring with them the most widely varied backgrounds. There is a tendency, therefore, to assume that students start their graduate careers with little usable knowledge of economics and with little common experience in other fields. The training of an economist from first principles to the doctorate, then, occurs largely in the graduate years.

In my judgment, firm but gradual action should be taken to stiffen the substantive admission requirements. In the near future this could be done by a more rigorous policy of requiring students to make up deficiencies after admission to graduate school and by more rigorous standards for the master's degree. In the longer run, I am inclined to think that the profession should work toward the formulation of certain minimal standards for the content of the undergraduate major, and toward the requirement of the equivalent of this major for admission to graduate study of economics. There is no legitimate excuse for the wide diversity of preparation which now characterizes the graduate student bodies in most departments of economics.

While it is clear that not all of this diversity of background can or should be eliminated, certain minimal preparation might be insisted upon. The content of this minimum would be determined by deciding what things in the education of an economist can best be done prior to his admission to graduate school or what things after. In view of the long periods required by students to complete their doctorates in economics (on the average), a case can be made for getting as many things as possible out of the way before the graduate period.

In my judgment, an applicant should be prepared at the undergraduate level in principles of economics, elementary statistics, money and banking, intermediate economic theory, and in one or two other

[12] Among 358 present and former graduate students replying to my questionnaires, 216 (60 percent) majored as undergraduates in economics, another 41 (11 percent) in business, 37 (10 percent) in various social sciences outside economics, and the remainder in fields ranging from English to engineering. Cf. Sibley, *op. cit.*, pp. 68-71; also Sibley, "Education in Social Science and the Selection of Students for Training as Social Scientists," Social Science Research Council, *Items*, September 1951, pp. 25-29.

fields of economics. He should present a knowledge of mathematics through calculus and a rudimentary knowledge of the major concepts of accountancy. He should also have a breadth of knowledge, in fields outside economics, equivalent to that which the graduate of a good liberal arts college might be expected to have.

Background in fields outside economics is a crucial problem, in no sense secondary to background in economics. Many of those who argue that prior preparation in economics is unimportant do so on the ground that it is better for students to devote their undergraduate years to fields such as mathematics, history, sociology, government, philosophy, and foreign language—fields which are particularly helpful in the study of economics—rather than to economics itself. They argue that the student will be able to go further by building upon a broad background than by concentrating early on economics. There is much to be said for this point of view. Certainly, there is no merit in an undergraduate program consisting of course after course in economics and business to the virtual exclusion of other fields. However, the choice is not between the extremes. It is possible for a student to present a sound major in economics, including the basic courses mentioned above and several others, and still to acquire the desired breadth. This is the goal toward which admission policies should be directed.

As indicated above, the raising of admission standards cannot be done suddenly and without notice; otherwise the expectations of the present generation of prospective graduate students will be unjustly disappointed. However with advance notice, there is nothing to prevent an early but gradual stiffening of policy regarding the repair of deficiencies. Several universities already scrutinize candidates' backgrounds carefully and require that indicated deficiencies be made up promptly and without credit. One university has a special intensive course in economic theory, carrying no graduate credit, for those not yet prepared to take the standard graduate course. Other institutions having less rigorous policies might well consider tightening up. The requirements for the master's degree also might be raised so that the award of that degree would signify that the candidate had not only met all requirements for the degree itself but also had removed deficiencies in his background.

But the policy of requiring students to make up deficiencies should be regarded as no more than an expedient. It is an inefficient and psychologically undesirable way of handling the problem. Graduate advisers dislike the duty of assessing deficiencies and imposing the task of making them up. Students feel, quite rightly, that the making up of deficiencies is an unrewarding task which interferes with their immediate objectives. They are inclined, therefore, to shirk the job

their graduate studies if they suffer from deficiencies which are concurrently being repaired as they can if their preparation is adequate prior to graduate study. The only sound solution, ultimately, is to include the elements of an adequate preparation in the admission requirements. Students should be permitted to make up deficiencies concurrently with graduate study only if the deficiencies are slight or if there are exceptional circumstances. This would be possible and fair to all if the admission requirements for graduate study in economics were fully publicized.

Methods of Selection

In the selection of students prior to admission, the principal criteria are undergraduate grades, letters of recommendation, interviews, and tests scores. In practice, most universities rely heavily upon undergraduate grades and letters of recommendation; no doubt these will continue to be the principal basis for admission. Interviews are often found impracticable because of expense and inconvenience. Tests, like the Graduate Record Examinations, the Miller Analogies Test, and others are used by only a few departments and by them usually as an incidental or supplemental source of information.

The principal issue concerning methods of selection relates to the role of tests. Regardless of the particular admission policy being employed by any given institution, would more extensive use of tests aid in the selection of qualified graduate students prior to admission? A study of results from the Graduate Record Examinations indicates that these tests have been useful in predicting success in graduate school at several institutions and in many fields.[13] This study is based on experience at Columbia, Harvard, Indiana, Iowa, Michigan, Pittsburgh, Princeton, Vanderbilt, Wisconsin, and Yale. The results are not spectacular. Scores on the Graduate Record Examinations usually are not superior to undergraduate grades as predictors of graduate school success. Yet when the test scores are combined with undergraduate grades, the predictive ability is increased significantly. Even when the two factors are combined, however, the coefficients of multiple correlation seldom exceed .75 and are usually much below this figure.[14] Although tests have by no means made possible anything like certainty

[13] G. V. Lannholm and William B. Schrader, *Predicting Graduate School Success*, Educational Testing Service, Princeton, 1951. See also the earlier study: Carnegie Foundation for the Advancement of Teaching, *The Graduate Record Examination*, New York, 1941.

[14] The only data on the value of the Graduate Record Examination in predicting work in economics are from two studies at Harvard in 1939 based on samples of 24 and 60 students. Unlike investigations in most fields, these particular studies indicated that the use of test scores did not increase the ability to predict graduate school success over that with the use of college grades. In these studies the predictive value of college grades was

in the prediction of success in graduate school, it does not follow that they are useless. They do increase somewhat our ability to predict success and they may be justified on this ground alone. Moreover, by using tests and experimenting with them over a period of time, it may be possible to improve their predictive value.

But test scores are valuable not only for their predictive value but also because of what they reveal about the student—about his basic "intelligence," his mastery of economics, the breadth of his background, his strengths and weaknesses, and the gaps in his preparation. Some of these may not be highly correlated with success in graduate school but may nevertheless provide useful information for purposes of admissions, identifying deficiencies, student counselling, and later appraisals of the student. The new Advanced Economics Test which is part of the Graduate Record Examinations, impresses me as a very useful test, particularly if attention is to be given to the prior preparation in economics which the student brings to graduate school.[15]

But there is an even more important purpose to be served by tests administered prior to admission. They would help each department gain some knowledge of the quality of its applicants *relative* to those of other institutions and of its admission standards and policies *relative* to those of other universities. If the tests were to serve this purpose, it would be essential that all universities use identical tests; that all employ the same examining procedures; and that the scores of students applying, students admitted, and students rejected be made available by all institutions for purposes of comparison. The data could be made available in such a way as to conceal the identity of particular institutions.

In my judgment, it would be highly desirable to require that all prospective candidates for admission to graduate study in economics present scores on tests designed to yield measures of scholastic aptitude and proficiency in economics. The Aptitude Test and the Advanced Economics Test of the Graduate Record Examinations provide such measures and would be available to all candidates. Continuing studies of the results of these tests should be made, not only to check the validity of the tests, but also to check the validity of judgments made about students. I suspect, and this opinion has been frequently confirmed by others, that the evaluation of students in graduate school is much less discriminating than it should be. Graduate grades for example are notoriously undiscriminating. When correlations between scores on

[15] This test was devised by a committee chosen from a panel nominated by the American Economic Association. The Committee consisted of Professors Clark L. Allen, Kenneth E. Boulding, Mary Jean Bowman, Ben W. Lewis, and Joseph J. Spengler (chairman).

tests and success in graduate school are less than might be hoped, it is always possible that discrepancies may be due in part to inadequacies in faculty appraisal of graduate students, and not alone to inadequacies in the tests.

The Graduate Record Examinations program presents few administrative problems for the university and is reasonably convenient for the student. It is conducted entirely by the Educational Testing Service, a non-profit organization located at Princeton, New Jersey. Each student can take the test at or near his home. The fee is ordinarily paid by the student but can be borne by the institution on a reimbursable basis.[16]

Selection of Students after Admission

Though improvement can be made in the selection of students prior to admission, the fact remains that our ability to appraise the potential success of applicants is limited, and a very selective admission policy will almost surely result in errors in the form of denial of worthy candidates and admission of unqualified candidates. Therefore, as suggested earlier, a reasonably lenient admission policy is indicated for all but a few institutions. The major part of the selection process, then, must take place during the early graduate period after the actual performance of the student can be observed. Even in institutions with the most rigorous pre-admission selection, the weeding out of the unfit will be necessary.

Present Practices

Most graduate departments of economics have standards which the student must meet after admission if he is to remain in good standing. Among 61 reporting departments, these standards are as follows:

	Number of departments
Honors	1
B	38
B—	5
½ of work B or better	1
Not more than 6 hours of C	1
C	4
Pass a qualifying examination	3
Pass courses	8
Total	61

When a student falls below the standard, the penalty in about half the institutions is probation and in another half immediate dismissal.

[16] See Educational Testing Service, *National Program for Graduate School Selection: Prospectus for Deans and Advisers,* Princeton, 1951. A copy of this booklet should be in the files of every department chairman.

A few permit special examinations or repeating courses in fields in which the candidate has been deficient. More than two-thirds of the reporting departments indicate that they also make informal efforts, though personal advice and persuasion, to induce weak students to drop out even though they may have met the formal standards.

Student Mortality

That a substantial selection process takes place after admission to graduate study is indicated by the extent of student mortality. Precise figures on this subject are not available but I have tried to arrive at a very rough estimate by inference from a variety of data on enrollments, degrees awarded, percentage passing preliminary examinations, number of candidates preparing theses, and average residence between various points in the graduate program.

From these figures, I would guess that out of 100 students admitted to graduate standing in economics:

60 will be awarded the master's degree or will complete the first year of graduate work successfully
30 will proceed with further graduate work
20 will take preliminary examinations
17 will pass these examination
10 will receive the Ph.D.

I repeat that these are very rough estimates. They probably do not reflect the actual experience of any one institution because there are extremely wide differences.

Not all of the mortality is due to poor scholarship. Some of it is due to the fact that students achieve their study objectives before completing the Ph.D., that they secure attractive jobs, that they run out of money, that their health breaks, or that they lose interest. Apparently there is great difference among institutions in the causes of mortality. Some reported that all mortality of graduate students in economics is due to student failure to meet scholarly requirements; others said that all mortality may be ascribed to other factors; and others gave almost every possible answer between these extremes. I suspect, on the basis of these replies and my conversations on the subject, that few departments have made careful studies of student mortality or know what happens to the great bulk of graduate students who drop out at some point along the line. In particular there is little knowledge of the extent to which gifted students fall by the wayside for one reason or another.

Among the graduate professors who were queried about selection of students after admission, few thought present practice too rigorous and a substantial number thought it too lax. Their responses to a question regarding the present mortality rate were as follows:

	For first-year students[17]	For advanced students[18]
Too high	10%	3%
About right	56	49
Too low	33	43
No answer	1	5
Total	100	100

Many of those who thought mortality too low felt that there was laxity in the weeding out of poor students. From the answers to the question, however, one does not gain the impression of widespread or deep dissatisfaction with the process of student selection. There was greater concern, however, when the positive question was asked regarding present practice in the encouragement of the more capable students. Several mentioned the need of more financial assistance, of honors and awards, and of better counselling.

Selection Policy

There are several techniques which can be employed to implement a policy of rigorous selection after admission.

First, students whose undergraduate grades and test scores indicate some probability that they will be unable to earn a master's degree should be warned in advance. This warning can best be given systematically, in accordance with established rules, through some form of probationary status. Some universities, for example, place on "limited status" all graduate students whose undergraduate grades were not up to a specified standard. A student on limited status is then dropped if, at the end of his first term, he fails to make grades of a stated minimum.

Second, a formal qualifying examination can be given to all new graduate students at some specified time after admission. In the few universities now giving the qualifying, practice varies as to the interval after admission when it is given: in some, it is shortly after admission; in others, near the end of the first academic year. Wherever I encountered the qualifying examination, faculty members commended it highly as a device for screening students and discovering deficiencies and as a basis for counselling. The examinations are mainly of an "essay" type not far different in character (but at a lower level) from the traditional comprehensive written examinations for doctoral candidates.

Third, students not on probation who fail to make specified grades should be placed on probation, and those on probation who fail to

[17] Schedule IV: 61 respondents.

[18] Schedule VII: 59 respondents.

make the standard should be dropped. In order to use this device, it is necessary that students be required to take courses for credit and to write examinations in these courses.

Fourth, the requirements for the master's degree can be made a major device for screening students. If, as strongly advocated here, the status of the degree were raised and a thesis and comprehensive written and oral examination required, the procedures surrounding the granting of the master's degree would provide an excellent device for screening candidates. The examining committee could pass on two questions: whether the individual should be awarded the master's degree, and whether he should be permitted or encouraged to proceed further with graduate work.[19] After the master's degree, little selection of students should be required—beyond that which takes place in connection with the preliminary examination for the doctorate and the dissertation.[20]

A Note on Financial Assistance to Students

An important part of the recruitment and selection of graduate students is the use of scholarships, assistantships, and other forms of financial aid. The high degree to which graduate students of arts and sciences are subsidized in American universities is a phenomenon of great interest. It is curious that graduate students in these fields are singled out for aid which, on the whole, is denied students of law, medicine, dentistry, and other fields requiring long, arduous, and expensive training. What is it, for example, that makes a student of chemistry commonly eligible for financial assistance and a student of medicine not so eligible?[21] A careful investigation of this institutional quirk, which probably enables the graduate colleges of arts and sciences to draw outstanding talent far beyond what they could otherwise

[19] A less desirable alternative to the examination of master's candidates by a committee is the circularization of all staff members regarding each candidate requesting opinions as to whether he should be encouraged or permitted to go on.

[20] A special problem regarding the selection of candidates occurs when students transfer from one university to another after having completed some graduate work. Because of the difficulty of interpreting graduate grades and letters of recommendation, it is probably desirable to supplement these sources of information with undergraduate grades and test scores. Many students transfer after completion of the master's degree. This is frequently a desirable practice and should be encouraged. If the status of the master's degree were raised, and the requirements made fairly uniform throughout the country, the fact that a student had earned a master's degree would also provide considerable information about him. At present, however, in view of the low estate to which the master's degree has fallen, a student's possession of that degree signifies little. After admission, transfer students can be subjected to the various screening procedures such as probationary status, requirement of minimal grades, and qualifying examinations.

[21] For an interesting discussion of the finance of students see, Ernest Van den Haag, 'Higher Educationa on the Cuff," *Fortune*, 1952.

TABLE 21.—FINANCIAL ASSISTANCE TO FIRST-YEAR GRADUATE STUDENTS OF ECONOMICS, 1951–52[a]

command, is a subject that exceeds the bounds of this study.

Table 21 gives data on financial assistance during 1951-52 to first-year graduate students of economics at 38 universities. Of the 180 receiving assistance, 39 (22 percent) received tuition only and about 85 (47 percent) received tuition and $500 or more. A substantial number (57 or 32 percent) performed no services to their universities; the remainder were divided among teaching, research, and clerical duties.

Table 22 presents corresponding data on financial assistance to advanced graduate students at 27 universities. At these institutions assistance was given to 373 advanced students. The great majority of these received cash over and above tuition, most were serving as teachers, and most were employed half-time or more.

The number of first-year students receiving financial assistance at 33 reporting institutions was approximately 13 percent of the total graduate student body, and the number of advanced students receiving aid at 23 reporting institutions was about 30 percent of the total graduate student body.[22]

[22] The percentage of first-year and advanced graduate students receiving financial aid varied from 0 to 100 among the several institutions for which data were available. The distribution is as follows: (*see tabulation at bottom of next page*).

TABLE 22.—FINANCIAL ASSISTANCE TO ADVANCED GRADUATE STUDENTS OF ECONOMICS, 1951–52[a]

assistance was uniformly greater among advanced students or Ph.D.'s than among first-year students or masters.

Most universities require that graduate students who are employed as assistants carry a reduced load of graduate study. Practice as to the amount of reduction varies considerably (see table 24). The variation is particularly marked for students working full-time.

The view is sometimes expressed that the employment of graduate assistants is a form of exploitation or sweat-shop labor. At the other extreme, the view is often stated that the work of a graduate student constitutes a form of apprenticeship or an induction into the profession which is the most valuable part of his graduate experience. In general, opinion in the profession is much closer to the second of these views than to the first. However, one's judgment on the educational and other values in graduate assistantships will depend on the type and amount of work and on the amount of remuneration.

On the question of whether universities should provide financial aid, graduate professors of economics are strongly and almost unanimously

TABLE 24.—GRADUATE LOAD PERMITTED STUDENTS WHO ARE EMPLOYED AS ASSISTANTS[a]

favorable. When asked about the objectives of this aid, the replies were as follows:

To encourage students to enter graduate study in economics who otherwise would not go on to advanced work	74%
To ease the financial strain of graduate students so that they may devote themselves more fully to their studies	77%
To insure an adequate flow of first-year graduate students to the department	40%
To obtain the services of graduate students for teaching, research, and other departmental duties	34%
To give graduate students an apprenticeship in professional work	45%

Most respondents thought that several of these objectives could be achieved concurrently, and therefore that the provision of assistant-

ships and scholarships for graduate students is a highly desirable practice.

When asked whether there are elements of exploitation in the provision of assistantships, the large majority of the professors thought not, and many of these felt that there are valuable educational values to be gained. Most of the few who thought there is exploitation in the assistantship system felt that the experience is good but that graduate students are underpaid for it. A considerable number, however, raised questions about *teaching* assistantships—not from the point of view of the assistant teachers but from the standpoint of their undergraduate students. In personal conversations on this subject I found a considerable number of professors who feel that the assistantship system involves an excessive sacrifice of undergraduate education for the sake of attracting graduate students or of cutting instructional costs. Most of the suggestions for improvement of the assistantship system centered around higher pay, requiring less work (particularly less routine or menial work), more careful selection of assistants, and more careful supervision of assistants.[23] It was clear from these replies, however, that most professors regarded the assistantship system as desirable.

When present and former graduate students who had had assistantships were asked their opinion concerning the value to them of the work required, the responses were highly favorable, as follows:[24]

Contributed materially	61%
Contributed some	13
Neutral	7
Diverted too much time, but contributed	10
Diverted too much time, but not serious	2
Diverted too much time, a serious problem	7
Total	100

It is apparent that the system of financial aid now in operation has strong support from both faculty and students. My principal recommendation is that financial aid be administered, so far as possible, with the purpose of discovering, encouraging and developing superior talent. This would suggest substantial allotments to first-year students. My impression is that financial aid is often used to encourage maximum total enrollments of graduate students rather than to encourage the best students to enter graduate work and to pursue their studies to completion.

[23] See Chapter 10.

[24] Schedules IX and X: 358 respondents.

Chapter 7

SUBSTANTIVE CONTENT OF GRADUATE STUDY

In this and the following three chapters the content of graduate education in economics will be considered. This chapter is concerned with subject matter in economics and related areas; the following three chapters will deal respectively with the "tool" subjects, training for research, and training for college teaching.

The kind of subject matter in economics and related areas that finds its way into graduate curricula is a resultant of several factors. It is determined partly by the traditions of economic education, which surely exert a profound influence, and it is determined by current trends in the development of the field, by the nature of the problems which are presently demanding the attention of economists, and by the special intellectual interests of particular faculty members. The curriculum—both in the list of courses offered and in the content of courses—is constantly adapting to new developments in the field and to new conditions in the world. Yet a kind of stability and continuity is achieved as a product of well-established tradition.

Proliferation of Economics

Economics, like other branches of learning, has undergone remarkable change in the past generation. New areas have been opened up, old ones have been refined and elaborated, new tools of analysis have been introduced, and new sources of data have been provided. Much of this change has taken place as economics has faced up to contemporary problems created by world conflict, new technology, economic instability, and growth of power blocs.

A mere recital of some of the areas of economics in which important developments have occurred is impressive. Among them are: monopolistic competition; theory of the firm and administrative behavior; theory of national income and employment; fiscal policy; dynamic economics; theory of growth and development; national income accounting; national economic planning; econometrics and mathematical economics; input-output analysis; and application of public opinion and behavioral research to economic problems. To this list could be added the great proliferation of such fields as statistics, labor economics, international economics, agricultural economics, area studies, welfare economics, industrial organization, and demography.

These developments in economics have left their imprint on graduate curricula. The content of old courses has been changed, new ones have been added, and a few have been dropped. Even the rapid increase

in number and variety of courses at most universities may be attributed partly to changes in the intellectual content of the field. A check of the catalogs of 10 leading universities indicated that these institutions together listed 389 courses in economics available to graduate students in 1929 and 628 such courses in 1952, an increase of 61 percent.[1] The corresponding figures for strictly graduate courses (i.e., excluding courses open both to graduate and undergraduate students) were: 136 courses in 1929 and 332 in 1952, an increase of 144 percent.

Another effect of new developments in economics has been the introduction of new fields of specialization. Today it is not uncommon for doctoral students to offer, for their examinations, such fields as employment theory, national income accounting, or economic development—fields which were seldom regarded as specialties a generation ago.

But perhaps more important than these changes has been the introduction into economics of enormously greater refinement of detail and more elaborate technical apparatus. A generation ago, graduate students in most universities concentrated on mastering Marshall's *Principles* which was a kind of bible for economists; they studied a fairly non-mathematical and non-theoretical type of statistics; they read a discursive type of economic history and history of economic thought; and they specialized in several other fields, such as public utilities, money and banking, foreign trade, or labor, no one of which required highly specialized or difficult technique. Today, on the other hand, graduate students of economics are confronted with a vast array of concepts, techniques, and detailed theoretical constructions. They perforce live in a strange world of indifference maps, kinked demand curves, cross elasticity, marginal propensity to consume, liquidity preference, net national product, sampling error, linear programming, and input-output matrices. They spend much of their time gaining familiarity with specialized concepts and techniques, and their success as graduate students is gauged largely by the degree to which they master them.

The graduate student of a generation ago, having less technical detail to cope with, was perhaps able to devote more of his time to rounding out his general education, learning something about the related social disciplines, exploring philosophy, and acquiring historical and institutional knowledge. It is possible that his graduate studies were less hectic than those of his more recent successors and that he had more time to digest, to correlate, and to philosophize.

This may well be an exaggerated picture of the differences between

[1] The institutions included were Harvard, Illinois, Iowa, Michigan, New York, Ohio State, Princeton, Stanford, Wisconsin, and Yale. An effort was made to achieve full comparability of these figures for the two selected years. In some cases, this was difficult because of changes in administrative organization and in nomenclature. However, I believe the figures presented are reasonably accurate.

graduate study of a generation ago and today. As one of my critics has said, there was always too much to learn in economics, and some of the increasing emphasis on formal technique may be offset by decreasing emphasis in other areas, notably history of economic thought and institutional study. Yet I feel that the comparison is essentially correct; my impression is shared by many of the economists with whom I talked. Economics is not, however, unique in this respect. The proliferation of subject matter and increasing technicality which I have described apparently characterizes physics, chemistry, biology, psychology, and many other fields in which rapid scientific progress is occurring and in which there are many practical applications of new developments. A kind of Malthusian principle seems to be at work in which knowledge grows at a geometric ratio while the time that can be spent by students in learning it grows at no more than an arithmetic ratio. Some have suggested that the problem is unusually acute in economics—a field in which the empirical testing of theory is difficult. Since old theories are never disproved decisively the discipline experiences accretion without elimination.

The proliferation of subject-matter and the increasing technicality of economics is probably the underlying basis of most criticisms of the content of graduate education in economics today. Perhaps the most frequent of these criticisms is that we are trying to cram too much into our graduate students—more than they can be expected to assimilate in the few graduate years. The result, it is said, is superficial knowledge of many things but sound and thorough mastery of none.

A second and related criticism is that students are so completely immersed in learning the technicalities of the field, and are under such great pressure to do so, that they do no longer have time to grasp the full significance of what they are learning nor the opportunity to gather in a background of broad historical, philosophical, and institutional insights which would give them the perspective and judgment necessary for successful work as economists. Since many of the technicalities of the field are in economic theory, this criticism sometimes takes the form of an attack on what is termed the over-emphasis on theory at the expense of the so-called applied fields. The theoretical bias is said to extend even to the courses which were once approached largely by historical and institutional methods, e.g., public finance, international economics, and money and banking. The result, it is said, is a narrow-minded generation of economists who are almost oblivious of anything that happened before 1929, who have little sense of politics or of history, who lack judgment, who are unable to distinguish between the postulates of theory and the facts of the real world. Thus, it is concluded, the stress on technique, and the closely-related emphasis on

theory, has been carried too far. It is time to retrace our path toward a more equal balance between the technical-theoretical and the historical-philosophical-institutional approaches.[2] This second criticism was expressed to me by many persons—professors, graduate students, and employers of economists. It was implicit in Professor John H. Williams' presidential address before the American Economic Association in 1951.[3] That this opinion should be widespread was a distinct surprise to me because I had been expecting to hear more frequently the opposite contention, namely, that our training in the technicalities and in economic theory is not sufficiently rigorous.

A third criticism of current graduate education pertains to over-specialization. It is said that the inability of economists—either during their graduate years or later on—to master the entire intricate and ramified field leads to excessive and premature specialization. It is recognized that this specialization may be unavoidable, since no man may be expected to master the whole field, yet there is a vague sense of uneasiness based on the feeling that students do not achieve the desired breadth of view. No doubt this attitude derives from the sense of interrelatedness of economic phenomena which most older economists regard as the very essence of the discipline. They feel that the economy, to be understood, must be viewed as a system in its entirety, and that excessive specialization destroys or blurs its systemic nature. Such critics, therefore, tend to deplore the present state of the discipline and to hope for the second coming of a John Stuart Mill or an Alfred Marshall to fit the pieces together into one intellectually satisfying—and at the same time reasonably non-mathematical—system. Some are optimistic and look for the new messiah to do his work in the next few years. Others, more pessimistic, feel that the science has advanced in so many directions and on so many fronts that a new synthesis is no longer feasible. According to this latter view, the economic generalist will soon become as scarce and as anachronistic as a Physiocrat or a Manchester Liberal.

The proliferation and "technicalization" of economics raises significant issues concerning the content of the graduate program. Should there be a common core and what should be its nature? What should be the role of economic theory? of statistics? of economic history? How much breadth should be expected? To what extent is specialization permissible? These are the questions to be considered in the remainder of this chapter.

[2] A variant of the criticism that theory is over-emphasized is that theory is associated with left-wing ideological biases.

[3] "An Economist's Confessions," *American Economic Review*, Mar. 1952, pp. 1-23.

A Common Core

In Chapter 4, I suggested that a "common core" of essential content be required of all graduate students in economics who are candidates for the Ph.D. and a similar but less rigorous core be required of candidates for the master's degree. A great majority of graduate professors are favorable to such a common core. Their responses on the question of whether "certain courses should be taken or certain subject matter learned by all or most candidates" were as follows:

	For master's candidates[4]	For doctoral candidates[5]
Yes	72%	73%
Possibly	16	9
No	7	10
Uncertain	3	2
No answer	2	6
Total	100	100

Almost all of those favorable to the common core thought it should be formally required of all students. But on the question of the content of the core, there was near-agreement on only one subject, namely, economic theory. Table 25 presents a tabulation of replies to the question of what courses or fields *ought* to be in the core and also indicates the percentage of institutions in which each field is formally required or elected by the great majority of students. As shown in the table, economic theory is recommended by 90% or more of the respondent professors, is formally required in nearly two-thirds of the reporting institutions, and usually elected by students in most of the remaining institutions. A little more than half the responding professors are agreed on statistics and economic history for doctoral candidates; otherwise no field draws a majority vote for inclusion in the core. Apparently, many professors are dissatisfied with what they consider the inadequate emphasis being given to statistics and economic history because the percentage recommending these subjects for inclusion in the core is substantially higher than the percentage of institutions in which these subjects are required or usually elected. On the other hand, some of the professors apparently feel that history of economic thought is being overdone because the percentage voting for it is smaller than the percentage of institutions in which it is required or usually elected.

Additional opinion of graduate professors on the relative importance of various fields was obtained through questions regarding over- or under-emphasis (Table 26). A substantial percentage thought that

[4] Schedule IV: 61 respondents.

economic theory, statistics, and economic history are being under-emphasized in the study programs of their graduate students; and some also thought that monetary and banking theory, mathematical economics, and courses outside economics were being under-emphasized for their doctoral students. A significant percentage thought that economic theory, labor economics, and courses in applied economics were being over-emphasized.

Questions regarding the relative value of various courses and fields were also directed to present and former graduate students. The replies are summarized in table 27. It is evident that relatively high valuations are placed by present and former graduate students on economic theory and statistics. Economic history and history of economic thought are valued well below these two. Of some interest is the substantial percentage of former graduate students who regretted that they had not had courses in research methods or courses in philosophy or social sciences outside economics.

My inquiries regarding the "common core" lead to two conclusions: (1) almost everyone agrees there should be a required common core, but (2) economic theory is the only subject which all agree should be included. Regarding the inclusion of other subjects there are substantial differences of opinion—although there is strong support for

TABLE 26.—OPINIONS OF GRADUATE PROFESSORS REGARDING RELATIVE EMPHASIS ON VARIOUS COURSES OR FIELDS

statistics, economic history, history of economic thought, and monetary and banking theory. I suspect, on limited evidence, that there is considerable difference of opinion also on the *kind* of economic theory that should be included.

Despite this lack of unanimity, I feel strongly that there should be a well-established common core and that the profession should work toward general agreement on its content.

In developing the content of the core, it is essential to include only genuine fundamentals which *all* students should be expected to master, and to strip the core of non-essentials. The several courses should be worked out in sequential and integrated fashion with clear agreement among professors as to coverage, omissions, and relationships—thus insuring adequate coverage while avoiding duplication. Only in this way can the core serve its purpose without taking over an undue proportion of the curriculum. Incidentally, there are great differences among graduate departments in the degree of teamwork and cooperation among professors in the planning of their courses and examinations. In some, each staff member seems to be a law unto himself. He teaches

and holds students responsible for whatever he chooses without joint consultation or planning. In others, great care is apparently exercised in working out balanced, non-duplicating, and inclusive programs of studies. Needless to say, I strongly recommend the latter policy for the core courses. The traditional freedom of professors should be tempered by cooperation in the planning of the core. If there is to be unbridled freedom, it should be reserved for specialized courses lying outside the central nucleus.

The requirements in economics and related fields, as recommended in Chapter 4, and in the remainder of this chapter are summarized in table 28. These include the common core and other requirements. These requirements could be applied either by means of required courses or by means of comprehensive examinations. I recommend the latter method. The achievement of required proficiency in a field of knowledge should be distinguished from the passing of given courses. More-

over, students should be free to prepare for examinations not only by taking courses but also by independent study. In any event they should expect to do independent study beyond the requirements of courses. Nevertheless, I have indicated the requirements in terms of courses or equivalents in order to express the nature of the suggested requirement with some concreteness.

Apparently there is general agreement among graduate professors that requirements should be in terms of performance on examinations rather than passing of courses, yet many professors have told me that this distinction is not easy to apply in practice. Even with the best of intentions, there is a tendency for students to prepare for examinations almost exclusively by taking courses and an equally pronounced tend-

TABLE 28.—SUGGESTED SUBSTANTIVE REQUIREMENTS FOR GRADUATE STUDENTS IN ECONOMICS[a]

	For Ph.D. candidates	For master's candidates
Common core:		
Economic theory including value, distribution, money, employment, and other topics	Equivalent of two year courses with prerequisite of intermediate theory and undergraduate money and banking	Equivalent of one year course with prerequisite of intermediate theory and undergraduate money and banking
Economic history	Equivalent of one year course	None
History of economic thought	Equivalent of one half-year course	None
Statistics	Equivalent of one year course with prerequisite of undergraduate statistics	Equivalent of one half-year course with prerequisite of undergraduate statistics
Research methods	Equivalent of one half-year course or coverage in connection with other courses	None
Other substantive requirements:		
Selected special fields of economics	Two to four fields each represented by the equivalent of at least one year course for which undergraduate course is a prerequisite. Fields in the common core may be selected if advanced work is done over and above the core requirement	One field represented by the equivalent of one year course, or two fields each represented by the equivalent of one semester course
Other fields of economics	Knowledge of many fields equal to that which could be acquired by reading elementary survey textbooks	Knowledge of 3 additional fields equal to that which could be acquired from reading elementary survey textbooks
Fields outside economics	Background such as would be expected of a highly-educated man	Background such as would be expected of one who had completed undergraduate work in a good liberal arts college

[a] See pp. 42–4, 60–1.

ency for comprehensive examinations to be based largely on the content of courses.

Economic Theory

Perhaps the most difficult problem in selecting a suitable common core is to decide on the nature of the courses in economic theory. The difficulties arise chiefly from the fact that the field has been rapidly changing and growing. Most teachers are uncertain as to what should be included and what omitted, and are unsure as to the amount of technical detail that is desirable or necessary. In many departments there is dissatisfaction with present offerings in theory, and most professors are continuously revising and experimenting with their courses.

Unfortunately, I do not have any definite or detailed recipe for the content of the core offering in theory. I doubt if these offerings should or can be identical in all institutions. However, on the basis of many conversations and observations, I can make some fairly concrete suggestions.

First, the core in theory should be the equivalent of a one-year course for master's students and a two-year course for doctoral students. I am assuming that theory would include the following topics: production, value, distribution, general equilibrium, money, income, employment, and possibly others.[6]

Second, the core courses in theory should present a fairly conventional but up-to-date and integrated treatment of the subject. They should acquaint the student with some of the important modern literature and with current intellectual issues in the field, but should not pursue minor details, digressions, or fine-spun analysis very far. The adjective "conventional" was used to suggest that these courses should not be the occasion for professors to ride their hobbies or to display their virtuosity. Individualistic approaches or emphasis of specialties, which are entirely appropriate in their place, should be reserved for other courses. In the core courses in economic theory, the student should be permitted a broad but rigorous view of the field as it is generally understood and accepted in the profession at the time. This suggestion is relevant especially to those departments which are dominated by particular schools of thought or points of view. As one ardent institutionalist said to me: "We should teach conventional theory to our students, if for no other reason, so that they will be able to combat the stuff competently."

[6] Some of my critics feel that two years of theory for the aspirant Ph.D. is excessive as a minimal requirement. While I do not wish to be dogmatic on this I feel strongly that if theory is defined to include as many topics as I have indicated, it cannot be treated adequately for the purposes of doctoral students in less than two years. Many experienced professors support me in this view.

Third, the core courses in economic theory should not be expected to serve too many purposes, or too many classes of students. Otherwise there is danger that they will serve none adequately. In some institutions a single course in theory—usually a year course—is available to students offering economics as a minor, is a required course for graduate students in business administration, is the core course for graduate majors in economics, and is the most advanced work offered for those specializing in theory. I submit that no single course can serve all these purposes. If the attempt is made, economics majors are almost certain to be short-changed.

This problem is particularly acute with reference to graduate students in business administration. In some institutions, these students are formally handled as majors in economics and are required to stand an examination in theory. Being practical-minded persons, they resent this requirement; in particular, they and their professors are resentful when failure in theory blocks their progress toward an advanced degree. Then, in order to avoid internecine trouble or to avoid losing the business administration students, efforts are made to soften the basic theory courses to the detriment of the *bona fide* economics majors. In other institutions in which separate degrees are granted to majors in business administration, the same problem arises when economic theory is required of business administration students. If the theory courses are sufficiently rigorous to be appropriate for economics majors, objections will be heard from business administration; if the courses are modified to meet these objections, they will no longer be suitable for economics majors. My firm conviction is that there is only one proper solution to this problem. Sound courses for graduate economics majors, resting on a prerequisite of undergraduate economic theory and providing a rigorous exercise in the fundamentals of the subject, should be offered. All economics majors should be required to take these courses or their equivalent—master's candidates for one year and doctoral candidates for two years. They should be open to other students who are prepared for them, but without any concessions. If these courses do not meet the needs of minors, business administration students, and others, one or more special courses for these groups might well be organized, but no economics majors should be permitted to substitute the standards of these special courses for those of the core courses in theory intended for majors. The argument for separating the several classes of students in theory is strengthened since the theory needs of the students of business administration are probably rather different from those of economics majors. This raises the interesting question as to what kind of theory is appropriate for business students, but that is beyond the scope of this study.

Fourth, advanced courses in theory should be provided, beyond the core courses, for those who wish to offer theory as one of their special fields. In many institutions there is no provision for this need.

Fifth, the nature of the required work in economic theory should be such that its relevance would be evident to students regardless of their intended special fields or career objectives. In some institutions I noted the tendency of students to regard economic theory as a hurdle—something like the foreign language requirement—which must be surmounted but which is not considered relevant to one's major interest in corporation finance, labor economics, transportation, agricultural economics, or other applied fields. This condition is clearly deplorable. It is due partly to the manner in which theory is presented, and due partly to the manner in which other fields are treated. Many courses in theory are highly abstract and other-worldly, and many teachers of theory apparently make little effort to show how it is used in the solution of practical and intellectual problems. I believe that the best teachers of theory demonstrate its pertinence and usefulness. They draw upon historical and statistical illustrations. They show by example how theory is used in the solution of practical problems. They demonstrate its relation to empirical methods in the advancement of knowledge. For them, theory is not an intellectual exercise antiseptically removed from all contact with real problems and issues. Teachers in other fields also need to help in linking theory to other branches of economics. The various so-called applied fields differ in the extent to which they have traditionally drawn upon theory. Fields such as public utilities, transportation, corporation finance, economic history and labor have not ordinarily been closely linked with economic theory, whereas, fields such as international economics, money and banking, business cycles, and public finance have maintained very close ties with theory. It seems to me essential that students should be called upon to use theory, to varying extents, in all of their economic studies and should have repeatedly impressed upon them the indispensability of theory in all branches of economics. I particularly feel that the ties with theory should be much closer than they have customarily been in the core areas of economic history and statistics.

Economic History

The place of economic history as an intellectual discipline and as a part of graduate instruction is today both fluctuating and controversial. As indicated in table 25 a quarter of the respondent graduate professors thought it should be included as part of the core for master's candidates, and more than half thought it should be required of all doctoral candidates. In practice, economic history is required or usually

elected by master's students in only 12 percent and by doctoral candidates in 33 percent of the reporting institutions. This suggests that many professors feel that this field should be given a more prominent place in the graduate program than it has held in recent years; and in conversations I detected a widespread desire to devote more attention to economic history. I believe that economic history should be part of the core for Ph.D. candidates. It is doubtful, however, if there is sufficient time in the master's program for it to be a requirement.

The recent growth of interest in economic history is apparently a reaction to the trend of economics over the past twenty years when enormous emphasis was given to economic theory (including the theory of income and employment) and when the applied fields were preoccupied largely with pressing policy issues. The result, many think, has been the production of a generation of narrow economists who know little about events before 1929 and who lack the kind of perspective which can come only through the study of developments over long periods of time. In particular, it is held, recently-trained economists are unaware that current public problems and issues have been faced before; they fail to see the modern economy in relation to the broad historical developments of which it is only a temporary phase; they fail to recognize the difficulties of shaping our economic destinies or of predicting future events; they are unable to visualize the long periods of time required and the resistances encountered in bringing about economic change; they fail to comprehend the importance of non-economic variables in the course of economic development; they lack appreciation of the complexities of reality; and they do not understand the importance of changing institutional patterns in the determination of economic affairs. According to this view our present generation of graduate students, because of their preoccupation with theory based on limited postulates and their exclusive attention to problems covering a limited time span, are lacking in wisdom and judgment.

Many of those favoring the requirement of economic history endorsed it only on the condition that it be a certain kind of economic history—and they were deeply critical of the kind which has commonly been offered. In general, the complaints against the field were these: (1) that it tends to be a mere chronicle of more or less unrelated facts without any theoretical orientation—that it asks and answers no important general questions but merely recites a string of superficial events, and (2) that it is intellectually dull and lacking in challenge for the student. Obviously these complaints were not universal nor were they levelled against every course in economic history—yet they were sufficiently frequent to represent a solid block of opinion.

In my inquiries about economic history, I found that much experi-

mentation is in progress and that the actual courses being given vary widely among institutions. They differ in relative emphasis upon European, American, and "World" economic history. This often depends on the interests of the professors involved. Some of the courses are in the form largely of factual and detailed chronicles of events and developments; others attempt to organize the subject around broad themes such as "economic development" and to derive tentative generalizations about causation or process. The current interest in the field of economic development and foreign aid has stimulated this latter type of course. Some teachers of economic history are attempting to relate it to economic theory by using episodes in economic history to illustrate principles of economic theory and *vice versa*. In this way, they are trying to use economic history as a kind of laboratory for theory. Others are combining economic history and history of economic doctrine, and attempting to show the interrelations between the two. I was much impressed by several courses of this type, though I suspect that there are few economists who are equipped to do this successfully. Other teachers are emphasizing the use of quantitative data in the form of long statistical time series and are thus attempting to combine the inductive-historical and the inductive-statistical methods. Others try to stress episodes in economic history in which parallels or contrasts with present problems or developments can be found. Others consider the job of the economic historian to be that of tracing the institutional development of the whole economic system, and their courses tend to center around the rise and development of capitalism. These various approaches to the subject are not mutually exclusive, and there are many examples of attempts to achieve various combinations. The field is extremely broad and extensive, however, and it is not feasible to attempt to do all these things in a single year course.

I am not in a position to recommend any particular approach to economic history for purposes of the required core. I am sure that valuable courses worthy of inclusion in the core for Ph.D. candidates could be developed along several different lines, and that the particular type of course to be given in any institution must be related to the background and interests of the professor who is to give it. I find myself sympathetic toward the criticisms of conventional economic history and favorably disposed toward the efforts to join economic history more closely to economic theory, economic development, history of doctrine, and statistics. I believe that out of the current ferment in the field something exciting can be developed and that it could provide a needed antidote to the provincialism and lack of perspective which has emerged from the recent general preoccupation with theory and current public issues during the past several decades. At the moment the greatest

impediment to progress in economic history is the shortage of personnel in the field, that is, personnel sufficiently conversant with modern economic theory and statistics to offer courses which will be intellectually challenging and will contribute to the education of economists.[7]

A final comment is in order regarding the question frequently asked, whether graduate students in economics should not take general social and cultural history rather than economic history as given in economics departments. Surely no one would look with disfavor upon general history as a field worthy of study by graduate students of economics, and would recommend to any student that he acquire a broad historical background if possible. Certain courses in general history would be preferred to some courses in economic history. Yet, it is probable that economic history, given by persons trained in economics and emphasizing the economic issues of the past and the development of economic institutions, is peculiarly fitted to the needs of graduate students in economics. General history must be thought of as a desirable addition to, but not as a substitute for, economic history.

Statistics

The opinion that statistics belongs in the common core is widespread though not universal. About half the respondent professors recommend that it be included and in about a fourth of the reporting institutions it is required or usually elected (see table 25). Employers of economists in business and government also frequently mentioned statistics as a need (or lack of statistical training as a weakness) of newly-trained economists with master's degrees or Ph.D.'s.

My judgment is that statistics belongs in the common core as part of the training of all economists, and that the equivalent of a full year course should be required of both master's and Ph.D. candidates. The objectives of the core requirement in statistics should, however, transcend mere training in statistical technique. It should provide a thorough background in statistics from the point of view of scientific method and logic and it should give an understanding and appreciation of inductive method as the working partner of theory. On the technical side greater emphasis than has been customary should be given to the problems of collecting data as distinct from the problem of manipulating data once collected. The course should acquaint students with available sources of economic data and with some of the important statistical studies in economics. To accomplish these objectives, at least a full year course would be required.

[7] For a discussion of the role of economic history see *The Tasks of Economic History*, Supplement VII, 1947, *The Journal of Economic History*.

In these suggestions, there is no implication that the entire core course in statistics should be given within the department of economics, though it might be. There is much to be said for a division of labor in which the statistical technique and logic are taught by professionally-trained statisticians, while the availability, meaning, and uses of statistical data in economics are taught by economists. Moreover, the latter might be taught either in connection with courses in various substantive fields or as a separate course.

History of Economic Thought

History of economic thought is a traditional core course at many institutions. It is required or usually elected by Ph.D. students at three-quarters of the reporting institutions and by master's candidates at more than a third of the reporting institutions (table 25). However, from conversations at many institutions, I have gained the impression that it has declined in popularity. This impression is partially confirmed in table 25 which shows that the percentage of professors who believe it should be in the core is considerably less than the percentage of institutions at which it is required or usually elected. That it has declined in popularity is due not to the opinion that it is not worthwhile, but to the fact that in competition with other new and more technical fields it is being partially displaced.

For two reasons, it should not be in the core for master's students: first, the inclusion of history of doctrine will prevent the master's candidate, in the limited time at his disposal, from getting acquainted with more essential fundamentals; second, considerable maturity and knowledge of economics—more than most first-year students have—is required for adequate comprehension or appreciation of the field. Therefore, it had best be left, in most cases, for advanced students.

On the other hand, I believe that it should be part of the core for doctoral students. It is one of the better vehicles for teaching economic theory, for giving perspective on current theories, and for giving insight into reciprocal relationships between ideas and events. The experimental attempts of several institutions to correlate history of economic thought and economic history is an interesting innovation which should be encouraged and observed closely.

History of economic thought is also a vehicle for introducing students to the world of scholarship which Professor Viner has described as "the pursuit of broad and exact knowledge of the history of the working of the human mind as revealed in written records."[8] Professor Viner

[8] Jacob Viner, "A Modest Proposal for Some Stress on Scholarship in Graduate Training," Address before the Graduate Convocation, Brown University, June 3, 1950, *Brown University Papers* XXIV, p. 1.

has proposed "that graduate schools make a place in their programs, a modest place, but one not confined to the Humanities departments, for scholarship, and that they require or at least plead with their students, especially those who are destined to be college teachers, to devote to that part of the graduate school program a fraction, a modest fraction, of their attention."[9] For economics this laudable suggestion can be implemented only by introducing students to the history of economic doctrine. Professor Viner's point is, of course, that the demands of technical professionalism should not be permitted to crowd out interest in scholarship. One might add that scholarship, in the sense of conversance with the history of ideas and their influence, may be one of the ingredients in the education of competent professionals in a field like economics.

Professor Viner is not alone in his concern for scholarship. In response to a question on this subject, two-thirds of the responding graduate professors indicated that they consider it a responsibility to kindle the interest of students in scholarship in the sense in which the term is used by Professor Viner.[10]

Research Methods

"Research Methods" is a course with which several institutions are experimenting and which some professors are advocating should be part of the common core. The objectives of such a course are : (1) to help students become acquainted with logic and scientific method, the nature of hypotheses, evidence, meaning, and objectivity; (2) to acquaint students with the several methods of research or of advancing knowledge in economics; (3) to acquaint them with some important examples of research in economics; (4) to stimulate their interest in research; and (5) to give them practice in research.

These are laudable objectives which every department should attempt to achieve. There is more than one way, however, of achieving them. Existing courses in theory, history, and statistics can be used if the professors in these courses are alert to the need and have reached an accord on a content including attention to research methods. Or, by common understanding, research methods can be handled in connection with one of these courses—perhaps the theory course or, preferably, the statistics course. Or research methods might be handled by tutorial work or seminars in connection with the writing of theses. At some institutions, excellent results have been obtained from courses on the philosophy of science given in the philosophy departments and attended

[9] *Ibid.*, p. 3.

[10] Schedule VII: 59 respondents.

by students from many disciplines. A final alternative is to institute a special course in research methods in economics. Various institutions may find different alternatives feasible. However, because existing courses in statistics, economic history, and theory are already bulging with essential substantive content, some institutions may well choose to establish a new course devoted entirely to research methods.

The objection is sometimes offered that courses in methods are likely to be sterile and uninspiring. There is some validity in this objection and this is a strong argument for handling instruction in method in connection with other courses. However, the course in method need not be devoid of content. The section on logic and the philosophy of science can be most challenging if handled astutely; the course can draw on many actual research investigations which can be considered both from the point of view of method and content; and if students are given research problems, either preparatory to their dissertations or otherwise, they can gain important experience.

Breadth and Specialization

In addition to the common core consisting of theory, economic history, history of economic thought, statistics, and research methods—which would be specifically required of all students—I have suggested (see table 28) that each student should present several special fields of economics. These would be selected from a fairly long list of recognized special areas, the list varying among institutions according to the staff and facilities available. Students would be permitted to present fields included in the core as special fields. To do this, they would undertake study beyond that expected of all students. For example, if a student should elect economic history as a special field, he would be examined along with other students on economic history considered as part of the core; then he would also be examined on the additional work he had done in economic history considered as one of his special fields. Each student would presumably consider one of the selected fields his major area of specialization and within it would choose the topic for his thesis or dissertation.

I have also suggested the requirement of a broad knowledge of fields of economics other than those included within the common core or the elected special fields. Doctoral candidates would be expected to have at least some knowledge of all fields of economics and of business administration, and master's candidates a general knowledge of at least three fields outside the core and the elected special fields. (Most master's candidates with undergraduate majors in economics would presumably have been able to meet this requirement in their undergraduate years.) Knowledge of these areas should be at least the equivalent of

that which could be obtained by reading standard elementary survey textbooks. The purpose of this requirement would be to insure that students would be aware of the major concepts, terminology, and issues covering a wide area. It is difficult to imagine that a Ph.D. in economics could be granted to a candidate who was unaware of the implications of such concepts as purchasing power parity, equity capital, depreciation, discount, non-competing groups, closed shop, current ratio, disposable income, bank credit, dollar shortage, agricultural parity, basing point pricing, classified property tax, last-in-first-out, etc. This kind of general knowledge constitutes literacy for the professional economist. Graduate students should also be expected to have a substantial background in fields outside economics. A master's candidate should be expected to have a background in science, humanities, and social science at least as broad as that of one who had completed undergraduate work in a good liberal arts college in the upper third of his class. A doctoral candidate should have intellectual breadth considerably beyond this standard. He should have the rich intellectual background of a highly-educated and cultured man.

I believe that a major portion of the profession generally agrees with these standards for breadth of background in economics and other fields. In response to questions regarding specialization in particular fields of economics at the expense of broader coverage and regarding specialization in economics to the exclusion of outside subjects, respondent professors indicated strong preference for breadth over narrow specialization. A large majority felt that it is a responsibility of their departments and their institutions to help graduate students become broadly educated and well-rounded human beings (table 29). Those who demurred from this position did so chiefly on the grounds that breadth should have been achieved in the undergraduate years, that the whole educational task cannot be done during the brief graduate years, and that sound training in the student's special field should not be sacrificed to the quest of "breadth."[11]

Despite the rather general approval of "breadth," I gained the distinct impression that few departments actually enforce requirements calling for breadth *within* economics; and even fewer require breadth of background *outside* economics. I believe that these requirements should be recognized more specifically and enforced by means of ex-

[11] An interesting and witty discussion of specialization and breadth is contained in a paper by Professor George J. Stigler: "Specialism: a Dissenting Opinion," *Bulletin of the American Association of University Professors*, Winter 1951-52, pp. 650-56. Professor Stigler's thesis is (p. 650) "that the worship of the cosmopolitan mind is romantic foolishness." He is inveighing, however, against those who never specialize and not against breadth of background from which to pursue one's specialty. In general I agree with his position which is not inconsistent with the recommendations made here.

TABLE 29.—ATTITUDES OF GRADUATE PROFESSORS TOWARD DEPARTMENTAL RESPONSIBILITY FOR BREADTH OF BACKGROUND

	Master's candidates[a]	Ph.D. candidates[b]
Responsibility to assist and encourage graduate students to become broadly educated in the sense of having an understanding and appreciation of history, politics, science, philosophy, literature, art, history of ideas, etc.:		
Yes	60%	61%
Qualified	2	7
No	38	24
No answer	—	8
Total	100	100
Responsibility to provide an environment that is conducive to the development of the "whole man" including social, cultural, and recreational interests as well as intellectual:		
Yes	63%	51%
Qualified	6	8
No	28	29
No answer	3	12
Total	100	100
Responsibility to help graduate students achieve some appreciation of interdisciplinary relationships among the social sciences:		
Yes	71%	85%
Qualified	2	5
No	14	5
No answer	13	5
Total	100	100

[a] Schedule IV: 61 respondents.
[b] Schedule VII: 59 respondents.

aminations. An urgent task for the profession is to define standards for appropriate general background within and beyond economics and to develop procedures for implementing these standards.

At the moment, the principal means by which attention is given to fields outside economics is through the so-called "minor." About one-third of the reporting institutions require minor fields for master's candidates, and three-quarters require them for doctoral candidates. Most institutions not requiring minors permit students to elect one or more minor fields. In more than a third of the institutions, however, special fields within economics or business administration may be counted as minors. And in fact about 60 percent of the 1951-52 graduate students and nearly half of the former graduate students responding to my questionnaires reported that their minors had been in economics

or business. Thus, the purpose of encouraging or requiring work outside economics is by no means always fulfilled.

The philosophy underlying the minor field as a part of a graduate students' program is entirely sound. There are many cases where the combined study of two fields is appropriate and fruitful. I doubt, however, if the requirement of a minor completely meets the need for breadth of background in fields outside economics. This involves the continuation and amplification of a liberal arts education covering many fields. I believe that the only satisfactory solution is to decide specifically on the degree of breadth desired and to enforce this standard by examining candidates for advanced degrees specifically on their intellectual breadth. In this way, they will have the incentive to become broadly-educated persons before they offer themselves as candidates.

Theory vs. Empiricism

In considering the content of graduate education in economics, I have tried to suggest courses and requirements which would achieve a fair balance between theoretical and empirical studies. In the core, for example, the former is represented by economic theory and the latter by statistics and economic history. And in considering special fields and general background, I have tried to achieve a balance between the theoretical and the empirical. As a result of observing departments of economics in action, however, I have concluded that this balance is an extremely subtle affair, and is not automatically achieved merely by arranging a suitable distribution of courses and fields. The problem lies deeper than that.

It is my impression—I have little documentation—that the graduate departments of economics at different universities are very uneven with respect to the relative emphasis on the theoretical and the empirical aspects of economics.[12] The atmosphere in some departments conveys

[12] In response to a question regarding relative emphasis upon economic theory and upon "studies relating to facts, institutions, and economic policy," the replies of respondent graduate professors with reference to the balance in their own institutions were as follows (data from Schedules IV and VII):

	For Master's candidates	For Ph.D. candidates
Satisfactory balance	50%	36%
Theory heavily stressed as it should be	10	17
Theory over-stressed	10	15
Facts, institutions, and economic policy over-stressed	6	10
Need for closer integration of theory and applied fields	2	3
Other	15	14
Uncertain	2	2
No answer	5	3
Total	100	100

to students the impression that theory is important and glorious, and that institutional or historical or statistical or socio-psychological studies are pedestrian and suitable only for second-rate minds. In these institutions, the staff consists mainly of theoreticians, and even the courses in the so-called applied fields tend to be highly suffused with theory. The students of such departments tend, I fear, to become relatively narrow theorists—much more narrow than their teachers. Other departments consist mainly of professors interested in the various applied fields. The spirit of such departments is on the whole anti- or a-theoretical; courses in theory are given, to be sure, but the study of theory tends to be perfunctory—a hurdle to be surmounted and left behind.

In most departments, even those in which theoretical and empirical interests are superficially well-balanced, I felt that far too little attention was given to empirical *research* of the kind that asks important basic questions (not necessarily pretentious or comprehensive questions), formulates hypotheses, and seeks answers through acquiring and analyzing data. The result, I think, is that we are failing to turn out any sizeable proportion of students who are thoroughly trained in, or *motivated toward,* empirical investigation using institutional, historical, statistical, or socio-psychological data. Most academic economists are inclined, I think, to pursue theoretical studies or to concern themselves with problems of public policy. Their theoretical interests tend toward fairly comprehensive subjects such as monetary theory, business cycles, employment theory, price theory, etc., and their policy interests are directed toward problems at the highest level such as inflation, unemployment, monopoly, or labor relations. There is relatively much less empirical work of a more modest sort calculated to test specific hypotheses. To illustrate, much more attention has been given to the development of comprehensive monetary theories or to the discussion of high-level monetary policy than to empirical investigations such as the effect of changes in the rate of interest on business investment. And more attention has been given to the broad theories of employment or discussion of economic stabilization policy than to empirical inquiries into problems such as factors influencing the form of the consumption function.

I hasten to state that I am in no sense launching an attack on theory nor am I objecting to the consideration of public policy by economists. Theory is of prime importance to the profession and to students, and I have given it a key position in the proposed substantive requirements for graduate students. Also, I believe that economists should devote themselves to the formulation and criticism of public policy. I am merely making a plea that more attention be given by academic econo-

mists and their students to the less spectacular but none the less urgent tasks of collecting and analyzing empirical data and testing specific hypotheses. Both the theory and the policy recommendations of economists would become more substantial if founded upon a larger and more reliable base of empirical verification.

How can interest in empirical research be fostered? The answer to this question is not easy, especially as the intellectual habits and traditions of a profession do not change readily. The answer lies partly, I think, in drawing to our departments of economics more intellectually vigorous economists with strong interests in empirical research. Many of these persons are now found in the Federal government or in various research institutions where they are not in contact with students. As things now stand, the balance of intellectual vigor and influence in many departments of economics is held by those whose major interests are theoretical. There is need for adding equally effective and persuasive persons whose bent is toward empirical research.

In addition to a diversified faculty, the achievement of a balance between the theoretical and the empirical requires that the two approaches be integrated in many of the graduate courses. Everyone knows that theoretical and empirical methods are complementary and equally indispensable in the advancement of knowledge. This complementarity should become evident in many parts of the curriculum. The lines separating the study of theory, statistics, history, and the so-called applied courses should be blurred. The contributions of the several methods and points of view should be merged. There is room in theory courses for reference to inductive materials. In statistics, the relations between the inductive and deductive methods should be continuously in the forefront. In economic history, both theory and statistics should have ample play. And in applied courses, like public finance, the menu should consist of judicious combinations of history, current facts, statistical analysis, and theory. The student should be spared the kind of compartmentalization in which he studies exclusively theory at 8:00 A.M., exclusively statistics at 10:00 A.M., solely economic history at 2:00 P.M., and only public finance at 4:00 P.M.

It is to be hoped that the diversification of faculty and the integration of method within individual courses may help to arrest tendencies for economists, and whole departments of economics, to become on the one hand radically theoretical and lost in an unreal world of logical deductions from over-simplified postulates, or on the other hand adrift in a chartless sea of unordered facts. It is to be hoped that they would gain the analytical powers and the sense of the interrelatedness of things which derive from the study of theory, but at the same time gain a respect for facts, a feeling for empirical research, an apprecia-

tion of the difficulties of applying theory to practical problems, and an understanding of the infinite complexities of the real world.

It was the problem of achieving greater emphasis on the empirical aspects of economics that led to my suggestion that economic history, statistics, and research methods be included along with economic theory in the common core for Ph.D. candidates. One might add, also, that to achieve the objective, the courses in economic history and statistics should be made more intellectually exciting and challenging than they have typically been in the past.

In discussing with graduate professors the problem of the relative emphasis on theoretical and empirical aspects of economics in graduate education, many agreed that a more equal balance is desirable, but questioned whether a practicable solution could easily be found. It was pointed out, quite rightly, that economic theory is the absolutely indispensable element in the education of economists. Nothing can be done without it. The problem, they pointed out, is whether anything significant can be done toward strengthening the empirical side without sacrificing theory. As one professor said, "Learning the requisite theory requires most of the student's time during his brief graduate period. We would be glad to introduce more institutional, historical, statistical, and socio-psychological materials and more research method. But to do so would cut squarely into the amount of time available for theory and prevent us from doing a good job in that most essential area. Moreover, we have fought for a long time to gain an adequate place in the curriculum, and in the interests of students, for theory, and we should hesitate to retreat just as victory is ours. The only solution would seem to be to lengthen the graduate period, but no one is enthusiastic about that. Therefore, the only solution would seem to be to make the best of a bad situation and to continue the emphasis on theory." I do not agree that this is an insoluble dilemma; I think, however, that it is a difficult problem, and that many departments should carefully consider the relationship between the theoretical and the empirical in their educational programs, and should plan their future staff and curricula with a view to redressing any imbalance that is found.

Chapter 8

RESEARCH TOOLS AND VERBAL SKILLS

In the discussion of "objectives and standards" (chapter 4), it was assumed that the important tools of research in economics include foreign languages, mathematics, law, accountancy, socio-psychological techniques, historical techniques, and possibly others.[1] It was proposed

TABLE 30.—SUGGESTED REQUIREMENTS IN RESEARCH TOOLS AND VERBAL SKILLS FOR GRADUATE STUDENTS IN ECONOMICS[a]

	For Ph.D. candidates	For master's candidates
Research tools (foreign languages, mathematics, law, accountancy, socio-psychological techniques, historical techniques, etc.)	Ability to use one tool with high proficiency; understanding of the use of other tools	None
Verbal skills:		
Reading	Ability to read economic literature in common core and selected special fields except that involving unusual technical apparatus	Ability to read any of the easier literature in the common core and special fields
Writing[b]	Ability to write, for technically-trained or lay readers, brief or extended discourses	Ability to write brief or fairly extended discourses in special field
Speaking[b]	Ability to speak or discuss clearly and coherently before a class, seminar, public audience, or committee	Ability to present an economic subject before a class or small group and to explain a point in informal discussion

[a] See pp. 44–7, 61–2.
[b] The skills of writing and speaking are to be considered jointly; deficiency in one may be offset by excellence in the other. No candidate is to receive degree who is sub-standard in both.

(see pp. 44-5) (1) that each doctoral candidate should have a sufficient knowledge of all these tools to understand how each may be employed in economic research and to apppreciate the various ways in which knowledge of economics is advanced; and (2) that each doctoral candi-

[1] Statistics, research methods, and logic and scientific method—often considered under the heading of research tools—are not included in this list. They are considered part of the common core which was discussed in the preceding chapter.

date should be expected to achieve a genuine mastery of at least one of these research tools.[2] It was also suggested (pp. 45-7) that high levels of performance should be required of doctoral candidates in reading and in writing *or* speaking. Corresponding but less rigorous standards of proficiency in the verbal skills were recommended for master's candidates (pp. 61-2). These suggested requirements are summarized in table 30. In the remainder of this chapter, I shall discuss each of these suggested requirements.

Foreign Languages

Perhaps the most widely-discussed and controversial of the research tools are foreign languages. A foreign language requirement for master's candidates in economics is in force at 42 of 87 institutions for which data are available. Of these, 39 require proficiency in one—usually French or German, and 3 require 2 languages. In a few institutions the requirement applies only to certain students or it can be satisfied if the student has completed 2 years of undergraduate work in a language. Of 52 reporting institutions, all except two impose a foreign language requirement for doctoral candidates. The two exceptions employ a general "tool" requirement which *may* be satisfied by passing a foreign language examination. The following are the specific requirements in effect and the percentage of the 52 reporting institutions employing each:

Reading knowledge of two languages (usually French and German)	75%
Facility with one language or a dictionary knowledge of two	2
Reading knowledge of two languages or reading knowledge of one and knowledge of a tool subject	19
One language and mathematics	2
General tool requirement, language may be used to fulfill	2
Total	100

In the large majority of institutions, the doctoral student must satisfy the language requirement before he takes the preliminary examination or before he is admitted to formal candidacy for the degree. In most institutions, the department of economics has no part in the administration of the examinations. This is usually done by the modern language departments under the supervision of the graduate college. Six institutions indicated, however, that the department of economics selects foreign language materials for the examinations and two that the department administers the examinations "with considerable charity."

The opinions of professors about the foreign language requirements

[2] I suggested that there should be no corresponding requirement for master's candidates.

are mixed but predominantly unfavorable. On the question of whether a reading knowledge of at least one foreign language should be required of master's candidates in economics, the replies were as follows:[3]

Yes for all students	18%
Yes for some students	25
No	46
Uncertain	8
No answer	3
Total	100

Some of those favorable to the requirement commented that the study of foreign languages helps the student to master English or contributes to his general culture. Those who thought the requirement should be limited to "some students" indicated that they were thinking of students whose research or career interests will be advanced thereby, or who were expecting to proceed toward the Ph.D. They were thinking, in other words, that some students ought to have language skills, but that it should not be required of all students. Significantly, no respondent commented specifically that a foreign language should be required of all master's candidates because of its general usefulness to economists.

When heads of departments were asked if their doctoral candidates "obtain sufficient proficiency in the foreign languages to be able to use them effectively in research and study," 60 per cent said "no," and another 8 per cent were uncertain or equivocal. On the other hand, nearly a third responded affirmatively.[4]

Opinions of graduate professors as to what should be done about the foreign language requirement for doctoral candidates were highly mixed. The wide disparity of opinion on the subject probably explains the delay of reform when so many are dissatisfied with the *status quo*. Recommendations on the foreign language requirement for doctoral students are presented in table 31.

A third of the graduate professors favor retention of two languages—though few insist that these languages should be exclusively French and German. Two-thirds would depart from the traditional two languages; 18 percent would continue the requirement of two languages but with provision for the substitution of a "tool" for one of the languages; 5 percent would require the substitution of mathematics or statistics; and the remainder (37 percent) would reduce the requirement to one language or eliminate it altogether.

Apparently there is considerable dissatisfaction among graduate professors regarding the administration of the foreign language requirements. Whereas only a negligible number of economics departments

[a] Schedule VII: 59 respondents.

now administer these examinations, there is considerable sentiment in favor of greater departmental responsibility in this field. This opinion is based in part on the feeling that linguistic needs in economics differ from those in other fields and that the department should have a greater voice in the standards and the conduct of the examinations. In response to a question regarding differences in the linguistic needs of graduate students in economics as compared with those of other students, nearly three-fourths of the professors responding thought there are significant differences. Some thought the needs of economics students are less rigorous than those of other fields, others commented that language requirements should be closely related to the students' interests

and objectives. A few suggested that the economist's language needs are related more largely to the acquisition of data from original sources than to contact with the scientific literature of other countries, whereas the examinations and standards are set mainly with the latter objective in mind. Few professors indicated, however, that they regarded the foreign language problem as a serious one, and few of those who favor changes base their position on the ground that the language requirement represents a significant hurdle which interferes with scholastic progress and professional development of graduate students. Many said, however, that the problem would be serious if the requirements were not laxly administered.

When asked about the frequent suggestion that the foreign languages should be used in connection with assignments for courses and seminars, the professors were again divided. About half were favorable or mildly favorable, about a third unfavorable, and the remainder neutral or uncertain. In considering the responses to this question, I wondered what percentage of the respondent professors would themselves be able to do assignments in a foreign language. However, some modest efforts to integrate the foreign languages with economic study is made in about a third of the reporting institutions.

TABLE 32.—OPINIONS OF GRADUATE STUDENTS REGARDING FOREIGN LANGUAGE REQUIREMENTS

	Advanced graduate students in residence in 1951–52[a]	Former graduate students who received Ph.D.'s in 1939–40 or 1949–50[b]
Beneficial	19%	21%

Of no benefit	64	62
No answer	2	4
	100	100

[a] Schedule IX: 81 respondents.
[b] Schedule X: 164 respondents.

Present and former doctoral students are less favorable to the language requirements than their professors (see table 32). Only about one-fifth of them feel that the meeting of these requirements was beneficial to them and nearly two-thirds said flatly that they got no benefit from the ordeal.

The only possible generalizations regarding opinion among economists on the language requirements are (1) that there is widespread

(though not unanimous) dissatisfaction with present practice, and (2) that there are many proposals for reform. On a subject so controversial and on which opinion is so scattered, recommendations in a report of this kind cannot be presented with the weight of any solid block of opinion behind them. They can have status only as one man's opinions. Nevertheless, for what it may be worth, I shall present those opinions. Most of the discussion will refer to the language requirements for doctoral candidates.

In general, the arguments of those economists who are in favor of the traditional language requirements for doctoral students are: (1) that economists would have contact with foreign literature; (2) that they should have access to foreign sources of data; (3) that the study of foreign languages helps to improve the student's command of English, contributes to his general culture, and helps to overcome provincialism; (4) that the prospective world leadership of America makes it incumbent upon us to have economists who know foreign languages.

Anyone can agree with all of these arguments, as I do. But the issue is whether these objectives can be achieved sufficiently by means of the traditional type of foreign language requirement to justify imposing this requirement on all doctoral students. I feel strongly that the traditional language requirement does not accomplish any of these objectives to an appreciable degree, and that there is little justification for it. By meeting that requirement most students do not gain useful access to foreign literature or foreign sources of data, their command of English is not appreciably strengthened, their general culture and breadth of perspective is not widened as much as it might be by the expenditure of equal effort in other directions, and most of them do not in this way become capable of assisting in the discharge of America's international responsibilities. In short, the traditional system represents little more than an irritating and meaningless hurdle which interrupts a student's work just at the time when he is most strongly motivated toward his field. Moreover, it is damaging to the morale of graduate students to impose upon them an onerous requirement the value of which cannot be adequately defended, and which many professors quite openly scoff at.[5]

Most economists do not rely heavily on foreign literature. They find

[5] The attitude toward the traditional requirement is apparently much more favorable among graduate faculties in the natural sciences, linguistics, history, and humanities than it is among social scientists. Hence, in almost all graduate colleges, change is resisted. The reasons for the more favorable attitudes of those in linguistics, history, and humanities are obvious. The natural scientists find the languages valuable because much important scientific literature is available in German, French, and Russian. This literature can be translated with relative ease because nomenclature and symbolisms are often standardized and because scientific papers are characteristically brief.

the foreign literature lengthy and extremely difficult to translate. Some economists need foreign languages for access to sources of data such as foreign documents, periodicals, bank reports, etc. But this need is restricted to a small minority, and is by no means common to the entire profession. Therefore, economists as a group are less enthusiastic toward the universal language requirements than their colleagues in many other fields. But because they and other likeminded professional groups are in the minority, and because of general academic conservatism, the foreign language requirements are likely to remain at many institutions, in something like their present form, for years to come. Hence, a few rather obvious recommendations for operation within the present framework may be in order.

First, every encouragement should be given to students to meet the requirements early in their careers and, if possible, to prepare for their language examinations before entering graduate study.[6]

Second, departments of economics should take some interest in the foreign languages, help students prepare, stimulate their interest in achieving enough mastery of languages to be able to use them, and draw foreign language materials into courses and seminars. If students are to be required to meet the language requirements, departments should help to make them as meaningful and as agreeable as possible, rather than leaving the student to meet—entirely on his own devices and without encouragement—a requirement which many of his professors openly regard as futile.[7]

Third, strong efforts should be made to alleviate the burdens of foreign students who come to this country with the intention of studying economics, but find that much of their time is demanded by the study of French and German at a time when they have not even conquered English. At the very least, such students should be permitted to offer English as one of their foreign languages.

Fourth, as much as possible should be done within the conservative framework of graduate college rules to permit greater latitude in the choice of languages offered to satisfy the requirement. Merely on grounds of availability of an important literature, Russian, Italian, and any of the Scandinavian languages can be defended as substitutes for French or German. And on grounds of availability of source materials for the study of regional developments, international economics, etc., any literary language in the world might appropriately be chosen.

[6] Cf. Carl C. Brigham, *Examining Fellowship Applicants,* Social Science Research Council, Bulletin No. 23. p. 23. Dr. Brigham points out the futility of awarding fellowships and scholarships to graduate students who will have to spend much of their time in satisfying language requirements.

[7] Cf. "Report of Subcommittee on Language Requirements," *Report of Fourth Annual Meeting of the New England Conference on Graduate Education,* 1947.

Along this line, some institutions have fallen into the curious habit of assuming that if a student asks to substitute, in place of French or German, a language he happens to have studied, he is *prima facie* trying "to get away with something." Thus, in some institutions, Spanish may be substituted for French only if the student has *not* studied Spanish before. If he has studied Spanish, then he must be examined in French. This kind of attitude toward the languages is clearly nonsensical.

Fifth, if language requirements are to be retained, departments of economics should use their influence to stiffen the requirements so that students will acquire at least some useable linguistic skill. In many institutions, the requirements while consistently retained are at standards so low that the student has virtually nothing to show for his efforts. It would seem that if the task is to be done at all, it should be done well enough to produce a tangible benefit for the student.

But it is to be fervently hoped that present requirements can be modified. The alternatives, listed in an *ascending* order of preference are as follows:

I. Various arrangements involving two foreign languages with low standards such as now generally prevail and with various provisions for substitution (essentially the present system in most institutions)
   1. French and German, no substitutions
   2. French and German, with possibility of substituting another language for one of these
   3. French and German, with possibility of substituting other languages for either or both
   4. Two languages with possibility of substituting one research tool
   5. Two languages with possibility of substituting one research tool or one collateral field
   6. Two languages with possibility of substituting one collateral field
   7. Two research tools of which foreign language may be one or both

II. No requirement whatever

III. Any of the arrangements under I above but with exacting standards such that the language or tool or collateral field will become an important useable asset for the student.

IV. Various arrangements involving one foreign language, one research tool or one collateral field with exacting standards such that student will gain an important useable asset.

1. One collateral field
2. French or German
3. One foreign language to be chosen from any literary language in the world—the choice to be made in terms of the students' research interests and plans
4. One foreign language, other research tool, or collateral field
5. One foreign language or other research tool

This list does not, of course, cover all the possibilities, but it does indicate the range. The reader can easily fit other alternatives into the pattern. In general, the reasoning underlying the order of preference is this: the requirement of two languages or other subjects with the low standards that have become customary is worse than no requirement whatever. If we are to have such a requirement, as I think we should, then let us impose exacting standards so that it will result in tangible accomplishment for the student. But if we impose exacting standards for *two* subjects, this becomes more than the student can do and still meet the other essential demands on his time and energy. Therefore, the best solution is to require one subject with exacting standards. Of the subjects from which to choose, I recommend that they include any literary foreign language or any other important research tool. Among these other tools I should include mathematics, law, accountancy, socio-psychological techniques, and historical techniques.[8] I do not favor the inclusion of a collateral field such as sociology, political science, industrial management or anthropology, unless it can clearly be defended on the ground that it contributes to the student's *research* equipment. I feel that the requirement should be designed specifically to sharpen the student's research ability and proficiency, and should not be merely another minor field. In line with this thinking, I should recommend that the student always be required to defend his choice of a subject in terms of his research interests and plans.

These recommendations are based upon three general principles: (1) that whatever subject a student may elect or be called upon to offer, an exacting standard should be imposed such that when he has met the

[8] A few graduate departments of economics now require a rudimentary knowledge of accounting concepts. I concur in this requirement and have suggested that it be included in the admission requirements along with elementary mathematics (see p. 88) rather than in the degree requirements. In response to a question as to whether proficiency in tool subjects other than foreign languages should be required for advanced degrees, about two-thirds of the respondent professors mentioned mathematics, one-fourth mentioned accounting, one-fifth mentioned logic and scientific method, and a handful mentioned library techniques. Many thought of these, however, as substitutes for, rather than additions to, the foreign language requirements. At least one university has experimented with a special graduate course in accountancy designed expressly for students in economics. Another has experimented with a non-credit course in the use of the library and sources of data.

standard he will have a viable intellectual asset, (2) that the requirement should be oriented toward research and should quite specifically increase the student's research capacities, and (3) that the requirement should result in the production of a generation of economists having diverse research skills—some in mathematics, some in each of many foreign languages, some in historical research, etc.

When the term "exacting standards" is used, I have in mind, for example, that the student who offers a foreign language would be able to read any literature in the language with such facility and speed that it would be feasible for him to read technical books, government reports, and newspapers in the language. If he offered mathematics, he should be able to read the literature of mathematical economics and statistics with facility.

To meet this standard in only one field would probably involve more work than most students now devote to the foreign languages. In general, on the basis of numerous inquiries but no formal survey, I would guess that to meet the present low-standard requirements of French and German requires of most students the equivalent of perhaps 3 to 6 months of full-time work, the amount depending on the student's linguistic background and facility. This is probably insufficient time for achieving any worthwhile results from the requirement. I should think that standards might be thought of in terms of at least 6 months of full-time work—preferably more. If the student is permitted to invest this time in a subject which he feels of value, the resistance to the meeting of this requirement would be less than that now encountered with the present foreign language requirements which are often considered useless. In considering the amount of time required, it should be remembered that it is possible for students to prepare for these requirements during undergradaute years or before entering graduate study, so that ideally no time need be taken from graduate study in order to meet the requirement. Indeed, the profession should work unremittingly to encourage prospective students to prepare in the tool subjects before entering graduate study.

It is sometimes objected that a plan under which the student may elect a substitute for the foreign languages will result in the latter being squeezed out altogether. Whether this will be true will depend, of course, on the relative difficulty of the various alternative requirements and on the kind of advice students receive. Data based on experience at the University of Minnesota suggest that the languages do not necessarily disappear when other options are available. During the period from 1949 to 1951, 71 percent of the Ph.D. candidates at that institution (in all fields) had the option, in place of one of their language examinations, of presenting a research technique or a collateral

field. Yet only 24 percent of the candidates exercised this option.[9] The remaining 76 percent offered the customary two languages.

The above discussion has related exclusively to the language requirements for the doctorate. For the master's degree, I see no compelling arguments for requiring a foreign language or research tool (other than statistics which is considered under the common core). Much more important for master's candidates is to achieve a thorough grounding in economic theory and other fundamentals.

Mathematics

The increasing utilization of mathematics by economists has led to great interest in the inclusion of mathematics as one of the tools which graduate students should be required or advised to acquire. Already nearly a fourth of the reporting institutions permit doctoral candidates to substitute mathematics for one of the foreign languages (see p. 125), and several others impose mathematics requirements (usually "through calculus") in addition to the foreign language requirements. Many professors have indicated their concern about the problem of mathematics training and many departments are considering the requirement of mathematics in some form.

About two-thirds of the respondent graduate professors think that mathematics should be included as a requirement for the Ph.D. Most of these hold that this should be as a substitute for, rather than addition to, a foreign language requirement. Also about two-thirds of the respondent graduate professors think that mathematics should be required "for some or all" master's students.[10] In reply to a question about the present ability of doctoral candidates to use mathematics for economic analysis, the graduate professors responded as follows:[11]

Good		2%
Fair		41
Poor		44
Uncertain		7
No answer		6
	Total	100

To stimulate improvement in the mathematical skills of doctoral candidates, the respondent professors suggested that students be encouraged or required to take courses in mathematics, that examinations analogous to the foreign language examinations be given, that admis-

[9] University of Minnesota, *Graduate Faculty News Letter*, Dec. 10, 1951, p. 4. Among the research techniques and collateral fields presented were: mathematics, statistics, accounting, public opinion analysis, research methods in business analysis, methods in higher education, surgical technique, and experimental psychology.

[10] Schedule VII: 59 respondents.

[11] *Ibid.*

sion requirements include mathematics, or that key economics courses be pitched at a level that would require mathematics as a prerequisite. The great majority were opposed, however, to giving graduate credit for elementary courses in mathematics or other tool subjects.

Many present and former graduate students also indicated concern about mathematics. When asked about inadequacies in their earlier training, or in their graduate programs, more mentioned mathematics than any other subject.

My conversations with professors and graduate students indicated an unmistakable and profound interest in the problem of mathematics for economists. At the same time, there is great perplexity as to how to solve the problem, and rather general groping toward solutions. The difficulty, of course, is that there are no *easy* solutions. The effort to enforce standards of mathematical proficiency which many members of the profession believe are demanded by current developments in economics would add an onerous burden for both students and faculty—a burden so onerous that few have the courage to insist on it.

Opinions on the place of mathematics range from the view that it is unnecessary (and that those who use it in economic analysis are arrogant pretenders) to the view that every economist should be a thoroughly trained mathematician. Fortunately, a committee on the Mathematical Training of Social Scientists, including representatives from the interested professional associations, has been at work; also the Social Science Research Council has sponsored a committee to survey the role and uses of mathematics in various social science disciplines.[12] It is to be expected that the deliberations of these two groups will bring forth useful information and suggestions. My comments on the problem in advance of the reports of these committees may be little more than a useless act of supererogation.

My first assumption is that mathematics is a highly important and useful tool in economics both for economic analysis and for statistics, and that the problem of mathematical training is a serious one for which satisfactory answers are urgently needed. As the discipline is developing, and is almost certain to develop in the future, the demands for mathematical training will surely expand. It is not difficult to imagine that the relation of mathematics to economics may some day resemble that between mathematics and physics or engineering. This possibility is presaged not alone by developments in economics but also by the even more rapid and revolutionary developments in statistics.

[12] I am indebted to Professor William G. Madow, Professor of Mathematics at the University of Illinois, a member of these committees, for many suggestions. He should not, however, be held responsible for any of the conclusions or recommendations which follow.

At the present stage of the discipline, mathematical ability is needed by economists at three levels. First a few economists, but a steadily increasing number, should have a command of mathematical skills at the most stratospheric level. These people would be depended upon to develop the areas of mathematical economics, econometrics, and statistics. They would be qualified both to read the literature of these fields, to formulate problems for solution in mathematical terms, and to solve these problems. I shall call these *mathematical economists*. Second, a larger number of economists, whom I shall call *mathematical readers*,[13] should be able to read with comprehension a substantial portion of the mathematical and statistical literature, for example, *Econometrica*, the more abstract articles in the *Journal of the American Statistical Association*, or books in which ideas are presented in mathematical form such as Leontief, *Structure of American Industry;* Marshall, *Principles of Economics* (appendix); Samuelson, *Foundations of Economic Analysis*. Some of these mathematical readers, it would be hoped, might be able to set up problems so that a mathematical economist could translate them into mathematical form and solve them—in other words, to be able to use the services of mathematical economists intelligently and effectively.[14] Third, most economists (I should be willing to say *all* economists) should have a sufficient orientation in mathematical ideas, symbols, and mode of thought to make economic theory and statistics more intelligible and to permit them to read easily, with comprehension, and without "formula fright" books such as Stigler, *Theory of Price* and Boulding, *Economic Analysis* (Part IV). They should understand such simple ideas of algebra, geometry, and calculus as variable, function, equation, simultaneous equations, differential, integral, limit, vector, tangent, logarithm,

[13] The Social Science Research Council, in sponsoring its 1953 Summer Institute in Mathematics for Social Scientists, gave as the objectives of the Institute: "to equip students to (a) formulate social science problems in mathematical form, (b) read mathematical literature in their chosen fields, and (c) do further work in mathematics and statistics beyond the level of the calculus if they find need for this in connection with their work in social science."

[14] A critic writes: "You mention a second category of economists termed *mathematical readers*. I think you are a little too modest in your estimate of their abilities and creativeness in formulating economic problems mathematically. Many of the great figures in the history of mathematical economics have themselves probably fallen into this category as far as training is concerned. Jevons and Walras are two names that come to mind but one could enlarge the list. Such people make no pretense at being fully trained mathematicians, but having real abilities in the field of economic analysis and logico-mathematical thinking they are able to puzzle and puzzle and finally state in terms of mathematics their economic theories. I am sure that many in this category will turn out to be more fruitful workers than undergraduates who have concentrated in mathematics and who have been persuaded to go into the field of economics. Incidentally, you will inevitably find that the very best undergraduate mathematicians will not be the ones who gradually transfer into the fields of statistics and economics, I fear."

matrix, etc. To be sure, these concepts and ideas can be understood without reference to mathematical symbolism or manipulations, but they are much more clearly understood with a modicum of training and experience. Economics and statistics involve so largely the manipulation of quantitative variables and rely so heavily on algebraic and geometric formulations that it borders on stupidity for anyone to undertake serious study of economics at the graduate level without the kind of elementary mathematical background indicated. I shall now comment briefly on each of these three groups of economists as classified according to degree of proficiency in mathematics.

The principal problem with reference to the "mathematical economists" (those with a very high level of proficiency in mathematics), is to insure either that a substantial number of economists will be induced to acquire a high level of mathematical skills, or that a substantial number of persons with highly developed mathematical skills will be pursuaded to apply their knowledge to economics. If this does not happen, economics will almost surely lag behind other disciplines. It is difficult to induce economists to acquire a high order of mathematical skill. Few students of economics acquire a substantial mathematical background in their undergraduate years. By the time they reach graduate school and recognize the need and the opportunity, it is usually too late for them to afford the time and energy necessary to become proficient in mathematics—particularly in view of the fact that years of work are involved for which no graduate credit can be earned.[15] This brings us back to the trite, but nevertheless sound, proposal that more students should have substantial mathematical training as undergraduates and, in order to accomplish this, that more should begin mathematics early in their undergraduate careers. This raises a host of problems as to how to increase the number of students who come to graduate work with adequate prior preparation.

Another suggestion is to encourage students with substantial undergraduate work in mathematics to enter graduate study in economics.[16] There are beginnings of developments along this line. Mathematics departments are beginning to recognize more fully their relation to and responsibility toward the social sciences, and in some institutions are attempting to work more closely with the social sciences. I believe that economics departments might well take the initiative in developing closer liaison with mathematics departments (and possibly also with

[15] Cf. Paul A. Samuelson, "Economic Theory and Mathematics—an Appraisal," *American Economic Review* (supplement), May 1952, pp. 56-66.

[16] Of the group of 358 present and former graduate students responding to my questionnaires, 11, or 3 percent, indicated that their undergraduate major had been in mathematics or engineering. Some others no doubt had had considerable work in mathematics.

engineering colleges) to pave the way for an increasing flow of students with mathematical training into economics. Students with mathematical training should, however, be urged to enter economics only in those economics departments where the staff includes economists and statisticians with thorough mathematical training. These staff members are needed if the student is to learn how to combine mathematics and economics fruitfully.

My suggestions regarding the foreign languages and other research tools (see pp. 131-3) were intended to help in producing a larger flow of "mathematical readers." According to this suggestion, students would be permitted to elect mathematics as their research tool. If they did so, they would be expected to achieve a degree of proficiency such that they could read readily and with comprehension, the *Journal of the American Statistical Association, Econometrica,* and other mathematical literature. This is no mean requirement. To achieve this would involve at least as much effort as to attain the suggested standard in a foreign language. (Indeed, one of the obstacles to the election of mathematics as a tool subject might be its difficulty as compared with a foreign language or other tool.) As indicated, it would be expected that some of the students achieving a genuine reading knowledge of mathematics might in addition be able to formulate problems so that more highly-trained mathematicians could set them up and solve them. It would even be hoped that a few of the "mathematical readers" would themselves develop some ability in setting up problems in mathematical form or in solving them. On the other hand, students who had met the suggested requirement would have much broader and deeper mathematical training than the "math through calculus" which many are thinking of when they propose the substitution of mathematics for one of the required foreign languages.[17]

While it is desirable to increase the flow of mathematical economists and mathematical readers, it is surely not necessary—at least at this stage in the development of the discipline—that every economist should have mathematical training at either of these levels. A case can be made, however, for requiring all to have an understanding of basic mathematical ideas as a background for the ideas and logical processes underlying both economic theory and statistics.[18] This requirement could

[17] It is possible that all students offering economic theory or statistics as their major fields for the doctorate should become "mathematical readers."

[18] Dr. Carl C. Brigham in his 1935 study *Examining Fellowship Applicants* (Social Science Research Council, Bulletin No. 23) stated (p. 35): "It is hard to reconcile this rather general mathematical deficiency with notions of the nature of social science. Certain fields of economics, politics, psychology, and other social sciences are developing very rapidly in mathematical directions. Disregarding entirely the possibility of individual contributions to the development of new techniques, it is difficult to see how a person who has forgotten

be handled in at least three ways: (1) as an admission requirement, (2) as a prerequisite to the courses in statistics and/or theory, or (3) as a requirement to be met at some time in the graduate period. I strongly prefer the first of these alternatives. I believe that the profession cannot reasonably delay much longer in requiring for admission to graduate study a knowledge of elementary mathematical concepts. As a corollary to this, the graduate courses in statistics and theory should be pitched at a level which would require this knowledge as a prerequisite. At least during the transitional period when this requirement is being established, each graduate department should offer a course, without credit, in which the student might acquire the desired mathematical background without having to traverse the lengthy sequence of traditional and partially irrelevant elementary courses given in mathematics departments.[19] At several institutions, such courses have been or are being offered. On the whole when they have been well-taught and supported by the faculty, the response of students has been encouraging. At some institutions, the student response has been so great that there is some question as to whether it would not do more harm than good to impose a mathematics requirement. Graduate students can be made keenly aware of their mathematical needs and deficiencies and can be persuaded to do something about them voluntarily.

Verbal Communication

A frequent complaint against graduate students in economics is their alleged mediocrity in the use of written and spoken English.[20] Employers often refer to this defect, a surprising number of present and former graduate students speak regretfully of their lack of competence in the communication skills, and a large majority of graduate professors have complaints on this score. Table 33 presents a summary of

elementary algebra can even become *well read* in the field of social science. The committee is of the opinion that elementary mathematical tests should be given to all applicants and that the weight given to their scores on such tests should depend on their proposed programs of study. To attempt to turn more mathematically illiterate scholars into fields already overcrowded with intellects of similar constitution does not appear to be a profitable venture. With respect to the fundamentals of foreign languages and mathematics, the committee cannot afford to send their first-year fellows on to graduate schools in the plight of the *Puck* or *Punch* plumber who has to go back for his tools."

[19] Some mathematics departments are developing elementary semester or year courses which would serve this purpose very well. One of the courses most frequently mentioned in this connection is that given in the College at the University of Chicago. The textbook for this course is: E. P. Northrop and others, *Fundamental Mathematics* (3 volumes), 3 ed. University of Chicago Press, Chicago, 1949.

[20] In this discussion, I am not including ability to read economic literature, even though this was included as one of the required verbal skills (table 30). The reason for this omission is that ability to read is the one ability which is thoroughly tested under existing practices.

TABLE 33.—OPINIONS OF GRADUATE PROFESSORS REGARDING STUDENTS' ABILITIES IN VERBAL COMMUNICATIONS

	Master's candidates[a]		Ph.D. candidates[b]	
	Ability to write	Ability to speak	Ability to write	Ability to speak
Good	16%	20%	14%	19%
Fair	61	66	51	63
Poor	20	11	22	12
No answer	3	3	13	6
Total	100	100	100	100

[a] Schedule IV: 61 respondents.
[b] Schedule VII: 59 respondents.

the opinions of graduate professors on the writing and speaking abilities of their students. As shown in the table, about three-fourths of the responding professors thought that the ability of students to write and to speak is below par. When asked what ought to be done to overcome the deficiency, graduate professors responded with a variety of proposals as follows (the percentage refers to the relative number of professors mentioning each proposal):

1.	More emphasis on written and oral reports, on essay and oral examinations, and on organized discussion and seminars	26%
2.	Remedial clinics, special courses, or other special remedial measures	13
3.	Encouraging students, through informal counselling, to improve their writing and speaking	11
4.	Appraisal of students' work partly on the basis of oral or written presentation	7

A third of the respondent professors thought, however, that the problem should be handled at lower educational levels, and not in graduate school. This position presumably implies that proficiency in writing and speaking should be required for admission to graduate study, and that therefore these skills should not be a special concern of graduate faculties.

My own judgment is that the communications skills are of utmost importance to future economists, and that it is incumbent upon graduate faculties to give careful attention to the development of these skills. This job might be done partly through requiring a minimal standard of competence, in writing at least, for admissions. For example, admissions officers might examine some of the prospective graduate students' written work. If entrance examinations are given, the students' writing ability could easily be tested. But even if entrance requirements of this kind were imposed, it would still be desirable to develop further the students' skills during his graduate years.

In my conversations with graduate professors and students, I gained the distinct impression that a great deal of graduate study takes the form of reading and lecture courses in which students occupy relatively passive and absorptive roles as readers and listeners rather than active and creative roles as researchers, writers, speakers, and discussants. This was true even in many so-called seminars. While I would not go to the extreme of arguing that there is no place in graduate instruction for the lecture or for systematic assigned reading, yet I feel that true graduate instruction demands of the student a great deal of the active and creative pursuits I have mentioned. My first recommendation, then, is that steps be taken to insure that all graduate students have many opportunities for the active and creative type of educational experience. I believe that most departments would be well advised to appraise their graduate programs from this point of view.

Second, I have recommended that a thesis, or its equivalent, be required of all candidates for the master's degree. One of the strongest arguments for the thesis is that it provides the student with a rigorous test of his literary skill. The formalities surrounding the thesis provide strong incentives for him to do his best work, and from the individual guidance of his professor he should receive many helpful suggestions regarding writing.[21]

Third, all written and oral work of students should be graded partly on the basis of the quality of presentation.

Fourth, greater attention should be given to opportunities for genuine discussion of economic subjects among students and between faculty and students. In one university after another I was impressed by the apparent lack of vigorous intellectual discussion among students. Admittedly, for a variety of reasons, discussion is more difficult today than it was 15 or 20 years ago. But this does not eliminate the need for training students in the art of expressing themselves informally on economic subjects. The present situation calls for conscious efforts on the part of the faculty to provide opportunities and stimulus for greater and more frequent student discussion.

Finally, fifth, the experience of graduate students as research and teaching assistants can be helpful from the point of view of developing skill in the art of communication. This leads us, however, to the subject of the next two chapters.

[21] In order to give students practice in writing for lay audiences, a science department in one university has required each of its students to rewrite his dissertation in the form of an article suitable for publication in a popular periodical.

Chapter 9

RESEARCH TRAINING

In Chapter 4, I suggested that competence in research should be one of the objectives of graduate education in economics. With reference to the master's degree, I proposed that a candidate should be able to carry on limited research projects under general supervision, or to serve as a useful research assistant under the detailed supervision of a mature research worker. Similarly, with reference to the Ph.D., I suggested that a candidate should be able to assume considerable responsibility as a research worker both in the theoretical analysis of problems and in the carrying out of operations to test the hypotheses suggested by theory.[1]

Competence in research is not the sole objective of graduate education. It is an important objective in the master's program and a leading—perhaps major—objective in the doctoral program. That training in research is an essential ingredient of graduate education can be defended on two grounds: (1) that it is good to produce a flow of economists who are equipped and motivated to engage in research at various levels, and (2) because experience with the methods by which knowledge is extended is an essential element in the training of all economists who are to use the products of research, whether they are to serve in teaching, civil service, or other capacities. This point is so evident and so widely accepted as to require no further comment.

In considering the place of research training in the graduate program, I shall take up first some general considerations relating to the environment provided by graduate departments, and then deal specifically with the master's thesis and doctoral dissertation.

Research Environment

The most important weakness of many graduate departments of economics is a failure to create a *research environment* for graduate students. I mean by this an environment in which students are literally surrounded by research, in which they can scarcely avoid frequent and first-hand contact with scholarly investigation both as observers and as participants, and in which the spirit of inquiry is prevalent. Unhappily, in some institutions which offer graduate instruction in economics, the failure to provide such a research environment is due simply to the fact

[1] See pp. 47-8.

that little research of consequence is in progress. But even in those institutions where research flourishes, a favorable environment for graduate students is sometimes lacking because students have little first-hand contact with the ongoing research program either as observers or participants. In advancing these criticisms, I do not intend a blanket indictment of every graduate department of economics. Some have succeeded remarkably in integrating graduate students into a productive research program. But there are few departments which could not show improvement in this respect.

On the whole, the natural sciences have far surpassed economics in the creation of an environment favorable to research training. In these fields, research is actively practiced by most graduate professors almost as a matter of course. Students work daily in laboratories alongside their professors. They are aware of the various projects of professors and other students. They observe the objectives, the methods, the difficulties, and the results. In the process of daily living, they become conditioned and oriented toward research. Contrast the situation of the typical graduate student of economics. He often knows little about the research work of his professors and other graduate students except through occasional seminar papers. He engages in little research himself until he writes his thesis or dissertation. His work then tends to be an individualistic enterprise in which only he and, at infrequent intervals, his professor are concerned. There is little of the daily working together, the frequent consultation, the sharing of problems that characterizes many scientific laboratories. What I am suggesting is that graduate departments of economics should emulate, in spirit and practice, the research environment of the scientific laboratory.

How can this be done? First, a substantial amount of genuine research must be in progress. Second, students must have the opportunity to become intimately acquainted with this research—with its objectives, methods, difficulties, and results. This calls for seminars and discussions in which the students are observers and participants. It also requires close personal contacts between professors and students. Third, instruction in research methods must be given (perhaps, but not necessarily, by the introduction of special courses such as have been inaugurated at several institutions). Fourth, and most important, students must themselves engage actively in research. Only in the kind of research environment where these conditions are met are students likely to acquire favorable motivation toward research, understanding of its methods, ability to criticize the research findings of others, and research competence of their own.

A satisfactory research environment can be achieved without any special organization for the purpose. It is necessary only that staff

members be actively engaged in research; that graduate students participate actively in research—not only in connection with their theses and dissertations but also in other ways; and that there be adequate means for constant communication among staff members and students on research activities. In such an environment students would function as apprentices, gradually passing from simpler to more exacting tasks, and eventually on completion of the doctorate achieving a considerable competence as independent research workers. To provide useful apprenticeships for students, however, is not always automatic or easy. Some kinds of research, notably theoretical analysis, are not suited to work by more than one person. It is difficult to utilize inexperienced research assistants on any but routine clerical work from which educational returns are not great. Students come and go, and there is no assurance that projects started will be finished or will be finished in good time. It is often easier to do a job oneself than to explain to another how to do it and to supervise his efforts. It is often more efficient to hire a well-trained professional person than to utilize student labor. All of these factors tend to discourage efforts to assimilate students into the ongoing research programs of staff members. But despite difficulties, the need remains; and the need is so great that it is essential to find ways to adapt research programs to instructional requirements. Academic research is intended to advance knowledge, but it is also intended to contribute to the training of students. In the achieving of the first of these purposes, the second should not be ignored.

Organized Research

It is probable that organized research agencies, which are becoming increasingly common in our universities, offer promising possibilities for improving research training. These research agencies include the labor relations institutes, area study institutes, research centers, bureaus of business research, agricultural experiment stations contract research projects sponsored by governmental agencies, etc.[2] These agencies have staff, budgets, and ongoing programs. They often sponsor a variety of research enterprises including both individualistic and co-operative or "group" projects. When research training becomes one of their objectives—which unfortunately is not always the case—they provide an ideal setting in which graduate students can function as apprentices in research, and can be on the "inside" of an active program. It is not essential that graduate students be paid for their work in every case, though if finances permit such payment, pecuniary as

[2] Sometimes also close working relations are developed between departments of economics and outside private or public research institutions.

well as educational problems are solved in happy conjunction.[3]

With such organized agencies, combining the objectives of inquiry and training, the student is able to observe and participate in research conducted under conditions similar to those he will experience if he later becomes a research worker in government or business. He has an opportunity to become acquainted with the kind of research—especially empirical research—which transcends the limits of the traditional solitary scholar whose only facility is a library. He can receive the stimulus which comes from working as a member of a team. Indeed, the advantages are so great that there is doubt in my mind as to whether a graduate department of economics can afford to be without some type of organized research program. This would be a counterpart of the laboratory in the natural sciences.

I am not suggesting, however, that mere formal organization is enough. There are dozens of academic research institutes and bureaus which, though doubtless performing valuable functions, are not accomplishing the purposes here outlined. Some of them are not really engaged in research at all, and some are virtually inert. What is needed is an active organization engaged in genuine research, and providing opportunities for student participation.

It would be foolish to suggest that every department of economics should establish an organized research agency of particular specifications. Departments vary in history, structure, personnel, specialized interests, financial resources, and need. Some may be able to accomplish high-quality research training with no organization whatever. Nevertheless, to be more specific, I shall try to indicate some of the features of one kind of desirable research organization, and to suggest how it might function. I shall refer to it as an institute of economic research.[4]

An Institute of Economic Research

The institute would have a budget, a director, a staff, an office, research facilities, and a research program of its own. There would be close connections and considerable overlapping between the staffs of the institute and of the economics department. Members of the institute staff might teach part-time, and members of the teaching staff might join the institute on a part-time basis or full-time for temporary

[3] There is no reason for supposing that a graduate student in economics might not participate actively in a research project for graduate credit and without financial reward, just as a chemistry student may undertake research assignments without compensation. Decency would require, of course, that the student be given recognition for his contributions and not be exploited by assigning him tasks of little educational worth.

[4] Of course its scope might be limited to a particular area such as labor, international economics, public finance, business cycles, etc. However, there are advantages in not so restricting it to a narrowly specialized field.

periods. The program of the institute would be reviewed by a committee including members of the teaching staff. The director of the institute would be responsible to the chairman of the department. The institute, in other words, would be an integral part of the department. The importance of this close relationship is obvious if research training is to be one of the functions of the institute.

In carrying on its own research program, the institute would provide abundant opportunities for graduate students to observe and to participate. Ideally, it would provide research assistantships with stipends, but it should also provide a research workshop to provide practical experience for students who do not receive remuneration.

The institute should also facilitate the research of members of the teaching staff and of graduate students. It should encourage their research. It should provide technical assistance and advice, for example, on statistical problems. It should provide, for approved projects, facilities or funds for clerical assistance, machine tabulations, travel, survey expenses, books, etc. It should provide leadership and assistance in obtaining grants from foundations and government contracts, and it should be a clearing house for contacts with outside sources of funds. It should maintain facilities for communication among all staff members and students on research in progress—perhaps by sponsoring frequent research conferences, seminars, and discussions, and by duplicating and distributing research memoranda.[5]

Such an institute need not interfere with the research activities of staff members who work best independently, or who are engaged in the kind of scholarly endeavor which requires solitude. Its function would be to help and encourage where such help and encouragement are useful. Its duty would be to carry on its own research, to stimulate the research of others, and to create a research environment in which graduate students could learn from observation and participation. Such an institute would be the counterpart of the *laboratory* which has been so eminently successful in the natural sciences. Just as physicists need cyclotrons, electronic microscopes, and laboratory technicians, econo-

[5] Dr. Paul Webbink of the Social Science Research Council has enumerated 11 key functions of university research organization in the social sciences: (1) to assume responsibility for acceptance and expenditure of research funds from all sources, (2) to review project proposals and to handle solicitation of funds, (3) to appraise research needs in light of resources and personnel, (4) to provide guidance and counsel in the planning of research, (5) to give counsel in the execution of projects and appraisal of results, (6) to foster research talent, (7) to provide facilities, (8) to encourage communication and cooperation among the several social sciences, (9) to represent the social sciences in negotiations with the graduate college or central administration, (10) to record research progress, and (11) to aid in publication. See "University Organization for Social Science Research," Social Science Research Council, *Items,* June 1948, pp. 1-5. See also: Donald Young and Paul Webbink, "Current Problems of Council Concern in Research Organization," *Ibid.,* Sept. 1947, pp. 1-5.

mists need facilities for surveys, tabulation equipment, and clerks. Just as physicists require laboratories where professors and students work together in an atmosphere conducive to the relationship of apprentice to master, economists need organized research programs in which students can observe and take part. Adequate research training in economics requires more than the accumulation by a student of the required number of hours of course credit, to be followed by a few conferences with a professor regarding a thesis or dissertation plan, and then a lengthy and lonely period of poring over books in a library. This is not to suggest that books are useless or that library research is passé, but only that a department which pretends to train students in research ought to offer more than that.

It may be objected that the cost of a scheme such as is suggested would be prohibitive. There are several answers. First, many universities already have institutes or formalized research organizations of one kind or another.[6] Some of these are already performing the indicated functions or could be adapted to the need without great increases in cost. Second, the outlay from university funds need not be large; the modest support by a university can be handsomely augmented by research funds for worthy projects from foundations and government agencies. Third, if universities can afford the kind of money required for research in physics, chemistry, medicine, and other material sciences, there is no reason to suppose that they cannot afford the relatively modest amounts required for research in economics. The traditional view that economists require nothing more than books can no longer be sustained.

There are, of course, dangers in the suggested scheme. First, it is easy, in enthusiasm for organized research, to belittle the efforts of the lone scholar whose only tools are his own intellect and the writings of others. Many of the great contributions of economics have been made

[6] Of 53 reporting graduate departments, 31 (58 percent) indicated that they have special funds to support research. Of these, 20 departments reported amounts and sources as follows:

Amounts	*Number of departments*	*Sources*	*Number of departments*
$ 0— 3,000	4	The University	17
3,000— 10,000	5	Foundations	7
10,000— 20,000	4	Industry	6
20,000— 40,000	3	Government	5
40,000— 70,000	1		
70,000—100,000	1		
100,000—130,000	2		

Of the 53 reporting institutions, 29 indicated that they make a practice of assisting individual faculty members in their research. The kinds of assistance in the order of their frequency were: direct grants, provision of research or clerical assistants, reduced teaching loads or paid leaves of absence, and funds for travel and publication.

by men working with only these tools supplemented by their own acute powers of observation (Smith, Ricardo, Mill, Marshall, Keynes, and many others). The same thing can be said of physics. Einstein's great contributions resulted from no "organized" research project. Nevertheless, in both economics and physics there is a place for research utilizing laboratories, facilities, organization, and financial support. Second, efforts to obtain funds from outside sources may divert energies from research in which staff members are interested and consider important to whatever research outside agencies are willing to support. Universities might thus become mere "project centers" engaged in programmatic research to the neglect of their main functions in the advancement and dissemination of knowledge. Related to this is the danger that the prestige going to those staff members who raise or receive money for research projects may cause discouragement to those staff members whose talents or interests lie in other directions. These are genuine dangers, but they are not inevitable. Obviously, a research program should be operated with good judgment and a sense of proportion, and without bureaucratic control over the creative efforts of scholars. But it is better, at least for purposes of research training, to have narrow programmatic research in progress than none at all.

Empirical Research

A special aspect of the research environment in which graduate students are trained is the *content* of the research which they observe and in which they participate. My impression, though this is difficult to confirm, is that academic economic research is very heavily weighted toward the theoretical, the historical, the critical, the synthetic, and the appraisal of public policy; and in contrast relatively little emphasis is given to empirical research which seeks to obtain new facts useful for testing hypotheses. Most of the research is of a kind that can be done in a library; it is bookish and such data as are used are drawn from secondary sources. It is of course understandable that this should be so. The traditions of economics are scholarly and literary. Theory built upon certain exiomatic principles has always been its leading technique. Economists have drawn their facts from general observations of the market place and from statistical aggregates usually collected by governmental agencies. This has proved fruitful for many problems, and in no sense do I suggest abandonment of these lines of inquiry. I suspect, however, that the emphasis has developed through following lines of least resistance and least cost. It is easier, cheaper, and in some ways more satisfying, to conduct economic research from the library cubicle than it is to go to the outside world for facts. Thus generations of academic economists have studied the determination of prices on the

basis of conventional postulates about the behavior of firms; yet our knowledge of how firms actually behave is still rudimentary. Or thousands of academic economists have considered theories of employment involving hypothetical consumption functions while only dozens have labored to find the factors underlying the responses of consumers to changes in income.[7]

Some of the reluctance of economists to do detailed empirical research is, in my judgment, due to the desire to construct systems at the highest levels of abstraction, and to a wish to solve the world's practical problems at the highest levels of policy determination. While the problems of the world press for answers it seems futile and pedantic to conduct empirical research about the details of economic behavior. Yet it may not be possible to solve the larger problems until more reliable and more detailed knowledge about the real world is available.

Should not steps be taken to broaden the base of economic research, i. e., to increase the relative emphasis placed upon empirical research —particularly upon that branch of empirical research which is concerned with the behavior of people in their roles as consumers, workers, investors, business men, government officials, etc.?[8] Should not graduate students be exposed to, and become interested in, this kind of empirical research? Would not the profession be advanced if coming generations of economists would devote somewhat less of their research efforts to theory, history, problems of national policy, criticism, and syntheses, and more to the empirical study of human behavior in its economic aspects?[9]

If the answer to these questions is in the affirmative, then the case for the "institute of economic research" is strengthened. Empirical research requires funds, clerical assistance, facilities, technical services, and other aids which are not ordinarily available to the professor working without an organization to support his efforts. With the establishment of such institutes, a regularized method of financing and executing empirical research is provided.

[7] This methodological bias was particularly impressed upon me when I was recently asked to furnish a list of economists who are engaged in behavioral research. I found difficulty in naming a half dozen.

[8] It might be supposed that psychologists and sociologists could do the job for economists. But unhappily except in a few isolated cases, they have so far shown little interest in the economic aspects of human behavior. There is a kind of intellectual vacuum at the very foundation of economics and relatively little is being done to fill it.

[9] A significant aspect of the need for more concern with empirical and behavioral research is that training in research of this kind is highly useful to economists who are to be employed in government and business. One of the frequent criticisms of graduate students who enter these positions is that their interests and experience are not sufficiently oriented toward empirical research.

The Master's Thesis

In Chapter 4, I suggested that graduate students—even those who expect to proceed to the doctorate—should take the master's degree, and I have proposed certain standards for this degree. Among these standards are the following: (1) that each candidate should be prepared in at least one special field in addition to the common core; (2) that he should be able to write correctly and with logical organization brief or fairly extended discourses on subjects in his special field; and (3) that he should be able to carry on limited research projects under general supervision or serve as a useful research assistant. I recommended that each candidate should write a master's thesis or equivalent as preparation for meeting these requirements and as a test of his ability to do so.

This judgment is apparently confirmed by both practice and opinion in many departments of economics. Of 107 universities for which data are available, 86 (84 percent) require a master's thesis or essay of all master's candidates. Usually this thesis is considered to comprise about one-fifth of the total work for the degree. About two-thirds of responding graduate professors indicated that in their judgment all candidates should be required to write a master's thesis or essay.[10] And about three-fourths of these professors reported that they are reasonably satisfied with the functioning of the master's thesis in their departments. When asked if changes in the requirements and practices regarding the master's thesis are anticipated, only 2 of the respondent professors stated that the requirement may be dropped, and 4 more that the requirement may be changed in some respects. When asked what they thought the educational objectives of the master's thesis are, or should be, the respondent professors mentioned the following:

Experience in extended analysis
Experience in writing
Experience in research
Experience in reaching valid conclusions by independent study
Appreciation and understanding of research and scholarship
Acquiring knowledge of a specialized field
Training in research methods
Familiarity with source materials
Testing preparation for work toward the Ph.D.

When the professors were asked if they thought these objectives were being achieved to a reasonable degree, only 2 replied in the negative.

Not only are graduate professors well pleased with the educational

[10] Another 15 percent of the responding professors thought that some but not all candidates should be required to write a thesis (data from schedule IV: 61 respondents).

functioning of the master's thesis, but also a majority of graduate students who have written theses express satisfaction. When asked whether the writing of a master's thesis made an important contribution to their intellectual development, their responses were as follows:

		Present graduate students[11]	*Former graduate students*[12]
Yes		58%	72%
Yes, qualified		25	9
No		17	19
	Total	100	100

It can be argued that the master's thesis is not an essential part of graduate education. The objectives of graduate work in the early years can be achieved in other ways, for example, by seminar papers, papers written in connection with courses, oral reports, etc. There is no substitute, however, for creative, original, and independent work presented in carefully written reports and subjected to the criticism of professors and fellow students. The advantage of the thesis—and it is an overwhelming advantage—is that it has a tradition. It is thought of by both students and professors as a major task in which students are expected to do their very best. The customs of formal announcement of topics, clear and correct presentation, and deposit in a library gives the thesis a special status. It is likely to call forth greater efforts on the part of students and to elicit greater personal attention on the part of professors than other forms of written and oral work. The retention of the thesis is undoubtedly one way to help protect or reinstate the quality of graduate education and the prestige of the master's degree. Another advantage of the master's thesis is that it is usually written in residence where facilities and counsel can be readily available, whereas the doctoral dissertation is frequently written *in absentia*.

The difficulty with the master's thesis—especially in the departments having larger graduate enrollments—is that the burden of faculty supervision becomes very heavy. Hence there are understandable and perhaps unavoidable tendencies to reduce the emphasis on the master's thesis or, if the formal requirement is maintained, to reduce the amount of supervision.

That the problem of supervision is a real one was revealed not only by many conversations with graduate professors and students, but also by the responses of present and former graduate students to the question: "How might the writing of a master's thesis have been made more valuable to you?" Nearly half of the reporting graduate students in

[11] Schedule IX: 140 respondents.

[12] Schedule X: 218 respondents.

residence in 1951-52 (who had written master's theses) indicated some dissatisfaction with the amount or kind of supervision, counsel, discussion, and conferences which had been available to them. And one-third of the former graduate students indicated similar dissatisfaction.

The subject of teaching loads and other demands upon the time of professors will be considered later. At this point, it may be observed that some graduate professors are carrying burdens so heavy as to preclude their giving detailed supervision to master's candidates. For example, some of the most distinguished members of the profession are carrying 6 to 9 hours of classroom teaching and supervising as many as 25 to 30 Ph.D. dissertations at one time. These same men are often in frequent demand for consulting, speaking, and writing. So it is small wonder that the master's candidates are sometimes given hasty consideration. The complaint about inadequate supervision, however, comes partly from students who are working under heavily loaded professors. It comes also from those who are working with professors whose loads, superficially at least, would permit them to give careful attention to their master's students.

The conclusion is inescapable that the kind of close working relationship between professor and student which might yield large educational dividends is lacking in a large percentage of cases. Some departments do not allow time for their professors to give this kind of attention to students, or when the time is given, some professors apparently do not take the responsibility seriously. In my judgment, this is a serious problem. Departments, large and small, should re-examine their educational programs for first-year students to determine whether they are meeting their obligations, or whether they are merely acquiescing in the trend to convert the first graduate year into a fifth undergraduate year.

The Doctoral Dissertation

There is no serious question as to the desirability of retaining the doctoral dissertation as a major requirement for the Ph.D. Almost everyone is agreed that it should be continued in something like its present form. Both professors and former graduate students indicate overwhelming approval of the dissertation as a highly effective educational device.

At most institutions, the educational objective of the doctoral dissertation is to train students in independent research and in the orderly and effective presentation of results. It is also intended to increase the student's knowledge of a specialized field within economics.

In general, the dissertation is regarded as a major task which will occupy at least a full year of the student's time. Most departments adhere, in principle at least, to the traditional concept that the dis-

sertation should be an "important and original contribution to knowledge," though there is widespread skepticism as to whether this standard is or can be actually attained. The sheer size and diversity of the annual list of doctoral dissertations presented each autumn in the *American Economic Review* leads to skepticism as to whether all of these projects will ultimately come to something important and at the same time original. Yet, year after year, there is an amazing variety of interesting work in progress by doctoral candidates, and the net result in terms of the growth of these students, if not in the development of the science, is surely most gratifying. However, there are certain criticisms of present practice, and improvements are possible.

As already indicated, a major criticism is that the topics selected and the methods employed are heavily weighted toward library research conducted wth secondary sources of data by single unassisted research workers. There should be no blanket condemnation of such topics and methods; for many purposes and for many students, "lone-wolf" library research is entirely appropriate. Yet because of the greater ease and the relatively smaller cost of this type of project, there is almost surely a slighting of the type of projects which requires the collection and manipulation of primary data. This raises again the question of the research facilities and environment of the department in which the student functions. In my opinion, many departments would be well advised to encourage the integration of doctoral research into the organized research programs of the department. In other words, it should be possible for dissertations to be written in connection with the work of the "research institute" described above. In this way the student would be able to undertake research of an empirical type under adequate supervision and with essential facilities. Sometimes, but not necessarily, his dissertation could be part of a larger study. In these cases, he would be able to learn not only from his own specific task but also from close association with the work of others. In all cases, however, his work should be clearly identifiable and independent.

This raises the question, frequently faced in agricultural experiment stations and other research organizations, as to whether students should ever be paid for the research they do in connection with their master's theses or doctoral dissertations—or to put it another way, whether students should ever be permitted to present, as a thesis or dissertation, work which they have done in connection with an organized research program and for which they have been paid. The answer to this question is not clear. It raises issues regarding the equitable treatment of those students who do not receive compensation for their research. Discussions with many professors who have had experience in these matters suggests that there is no compelling reason for denying a stu-

dent the privilege of using in his dissertation research work for which he has been paid. There is little difference between this and a scholarship available during the period of preparing a thesis.

I should emphasize again that I am *not* suggesting that all dissertations should be part of organized research programs or that there is no place for the more conventional topics and methods. I am only pointing out that the organized research program provides a splendid way of promoting more empirical work, of making better research facilities available to students, of providing good supervision, and possibly of making available more financial assistance.

But regardless of whether a department has a research institute, I should strongly suggest that the range of research facilities available to doctoral candidates be enlarged to include more than a library. Many worthy doctoral projects require travel, clerical assistance, machine tabulations, field surveys, etc. Departments should have funds which could be made available to students for these purposes, and should encourage more students to undertake the kinds of projects which require these facilities. These things are the counterpart for economics of the laboratories which are so essential in the natural sciences. At present, only a handful of departments have funds available to support the research of doctoral candidates except for those candidates who receive outside grants (e.g., from the Social Science Research Council). Yet an overwhelming majority of professors believe that such aid should be provided. In my opinion this is a most urgent next step in improving the research training of economists.

It is sometimes possible for doctoral candidates to utilize in their dissertations research which they have done when employed in a business, a governmental agency, or a non academic research institution. Sometimes this works out well, though it has the disadvantage of all work *in absentia.* This raises the question of supervision of the doctoral dissertation.

Supervision of Doctoral Dissertations

For many reasons, the principal one being financial, many dissertations are written *in absentia.* Generally, this is an undesirable practice. It often means that the student gets little attention from his advisers, loses the stimulus of working in a university environment, divides his thought and energies between his job and his dissertation, and works without adequate library and other facilities. Moreover, the length of the period over which he is working on his dissertation is greatly extended so that the process becomes a burden, a bore, and a source of frustration. Many dissertations are not completed for this very reason. It is highly desirable in most cases for the dissertation to be completed,

If this is to be done, however, departments must encourage their students to remain during the writing of the dissertation. In many departments there is practically no such encouragement; it is regarded as normal procedure for students to leave when they pass their preliminary or general examinations. I believe that all departments should advise students unmistakably of the advantages of remaining in residence until the dissertation is near completion. Advice, however, may not be enough in view of the financial burdens faced by students. One solution, therefore, is to offer more scholarships or part-time graduate appointments to students who are in the final phase of their graduate work. This raises a difficult issue. Assuming that a department has a given sum for aid to graduate students, shall it be used to finance a larger number of students through the first two graduate years, or shall it be used to finance a smaller number of students through three years? Some institutions have quite consciously chosen the first of these alternatives. In my opinion, this is likely to be the wrong answer. It would be better to be more selective and to provide aid throughout the graduate careers of students.

Even if students receive scholarships or part-time appointments during the period when they are working on dissertations, the temptation to take full-time jobs paying several times the graduate stipends will be strong. So even here the solution requires encouragement or persuasion. Departments should attempt to create the attitude that it is normal for students to stay in residence until the dissertation is virtually complete, and that it is unusual or irregular to attempt to write dissertations *in absentia*. When students find it financially impossible to continue residence after passing the general examinations, they should be encouraged to return for additional residence at a later time.

It does not follow, however, that if the student remains in residence during the writing of his dissertation, he will automatically receive adequate guidance and supervision. One of the most frequent complaints of graduate students is that they get little assistance from their professors, and that they are delayed by the slowness of professors to read and criticize their work or by difficulty in seeing the professors at all except for perfunctory and infrequent visits of short duration. While the complaints are more numerous in the departments with large graduate enrollments and overburdened professors, the complaints are also found in institutions where graduate enrollments are relatively low. When former graduate students were asked how the writing of a doctoral dissertation might have been made more valuable, 60 percent (of 164 who had completed dissertations) responded that more or better supervision, conferences, discussion, etc., would have been help-

should lead departments to reconsider the teaching and other loads of professors on the one hand, and the obligations of professors to students on the other.

It is obvious that guidance and supervision can be overdone. The dissertation is supposed to be a measure of the student's ability to work *independently,* and not of his efficiency in carrying out the suggestions and elaborating on the ideas of his professor. Students vary in the amount of guidance they need. Nevertheless, graduate students, no less than other research workers, need the benefit of frequent criticism, suggestion, and discussion.

Scope and Content of Doctoral Dissertations

A criticism of many dissertations is that they are too long, that they deal with problems that are too comprehensive, and that they tend to become syntheses of other economists' ideas rather than reports of original research. I think there is little doubt that too much attention has been given to length; a tradition has developed that a dissertation in economics must be a sizeable tome. There is merit in current tendencies to permit students to present dissertations of article length, provided the quality and extent of work involved is up to standard and provided adequate documentation and description of methodology are presented. Length should be a function of subject and not an end in itself. Indeed the goal of originality would be more frequently attained if students did not feel a compulsion to produce a lengthy document.[13]

It is sometimes argued that the education of the student—especially his preparation for college teaching—will be advanced more fully if he writes a lengthy synthetic dissertation covering some broad subject than if he conducts research on a narrow topic and presents his results in the form of a research report. This raises a very fundamental issue. My own view is that the educational merit of a specific subject on which the student attempts to do original research is greater than that of a broad subject on which the student attempts to write a book. If the specific research is adequately done, the student will be required to understand the broad field of which it is a part just as thoroughly as though he had written a book on it. In addition, by pursuing the specific subject, he learns about the methods and nature of research. This he

[13] A critic writes: "The dissertation requirement—as it has been enforced—has contributed to lowering the standards of research in economics. The frequent insistence on length plus the burden on professors resulting from too many dissertations to supervise has led to low standards of quality. Sloppy work is accepted. The student regards this as evidence that this is an acceptable standard of quality in general, and proceeds to use it in future work. He leaves his graduate work with no real standards of workmanship. The dissertation requirement—properly enforced—could make a major contribution to raising standards of research. For this purpose, it is absolutely essential that emphasis be shifted from quantity to quality."

may never learn merely by reading and rearranging the writings of others. In these comments, I do not mean to generalize for all students or to insist that all dissertations should follow a particular rigid pattern. Yet I find difficulty in accepting the view that research on a specific and limited problem is narrowing in terms either of breadth of personality or breadth of knowledge. It can be so regarded only if it is assumed that the doctoral dissertation is to be the student's final creative effort. This is precisely what we should strive to avoid. His dissertation should represent one research effort made in the expectation that there are others to follow.

A special aspect of the scope or comprehensiveness of dissertation topics relates to the premium which the labor market for economists places upon the Ph.D. A student who elects a difficult or extensive topic requiring a long time to complete is placed at a disadvantage as compared with one who elects a fairly easy or restricted topic. Other things equal, the latter will receive his degree earlier and will move up the academic or other professional ladder sooner. By the same token, a student who does a careful and thorough job is placed at a disadvantage—at least in the short run—as compared with one who does the sloppiest acceptable job. Students therefore acquire the attitude that the dissertation is something "to try to get over with" as soon as possible. Many have expressed this attitude to me quite bluntly.

I am not sure that there is any solution to this problem except the one of maintaining adequate minimal standards. Surely there is little hope of establishing a nice equality in the amount of work involved in all dissertation topics. One suggestion has been made, namely, that the degree be awarded after a student has made significant *progress* (adequately reported) on a major subject comparable to that required for *completion* of a minor topic.

Publication of Doctoral Dissertations

I have already indicated in Chapter 4 certain doubts about the practicability of mandatory publication.[14] Yet it must be admitted that publication may serve two useful purposes: (1) it may help to maintain standards, since both professors and students will be more meticulous regarding a document that is to be published than one which is to be limited to typescript and buried in a library; (2) it may help to disseminate the results of doctoral research.[15]

As a compromise solution to the publication problem, would it be possible to publish abstracts—perhaps up to 25 pages in length—of

[14] See pp. 48-50.

[15] Microfilming has helped on this, though it is not yet a full solution.

Chapter 10

TEACHER TRAINING

A wholesome development in the field of graduate education is the increasing concern for the preparation of men and women for college teaching. Deans of graduate schools and others engaged in education at the graduate level are asking themselves whether conventional graduate education, with its emphasis on specialized "research," is well-suited to the preparation of college teachers. Since a substantial portion of their students become college teachers (in some fields the great majority enter college teaching),[1] the question quite naturally arises as to whether a program of training oriented toward research is really suitable for persons whose professional lives will be spent as teachers. The question becomes especially pertinent in view of the fact that the Ph.D. has become a union card for college teachers, and is therefore sought by thousands of persons who have no intention of devoting their lives to research.

The problem is also significant for departments of economics. It is true that many graduate students of economics ultimately serve in government, business, and private research organizations; yet a large number of them enter college teaching. A Committee of the American Economics Association on the Teaching of Undergraduate Economics considered the question of the training of teachers, but decided that a comprehensive study of this subject "would have to concern itself with the complicated business of our graduate schools, and would necessarily be coextensive with the whole subject of graduate instruction in economics."[2] Accordingly, in its report of December 1949, this group recommended that "a committee be appointed to study and report on graduate training in economics, the report to consider both the development of scholarly techniques and the development of competent teachers." The present study is a result of that recommendation.

Issues and Points of View

In chapter 3, I suggested the following minimal standards regarding teaching ability: (1) at the time of receiving his master's degree, a student should be able to teach, under supervision and with time for preparation, the first undergraduate course in principles of economics;

[1] See p. 10.

[2] Horace Taylor (editor), *The Teaching of Undergraduate Economics, American Economic Review* (supplement), Dec. 1950, p. x.

(2) at the completion of the Ph.D., the candidate should be prepared to teach, at a level of proficiency acceptable in a leading university or college, principles of economics, the first undergraduate course in his special field, and (given time for preparation) intermediate economic theory. These standards were intended to apply to all students whether or not they expected to enter college teaching. They were proposed on the ground that a candidate who would be unable to meet these standards would be handicapped not only as a teacher but also in other jobs within the profession. These other jobs also require basic knowledge of economics and the ability to impart it to others. Almost all economists are in some sense teachers. Thus it is entirely appropriate that practically all should be expected to have some competence as teachers, just as all should be expected to have some competence in research. According to this view, about the same type of training is suitable for all graduate students in economics regardless of their career objectives. Those who expect to enter teaching should be trained in research and those who expect to engage in research should achieve a certain competence in teaching.

There are many who take issue, in varying degrees, with this position. At the extreme are those who believe that the type of education suitable for college teachers is markedly different from that suitable for research workers, and that the orientation of graduate education toward research detracts seriously from its usefulness in the training of teachers. It is held that this is particularly serious because most students —at least those at the Ph.D. level—do in fact enter college teaching. The main criticism levelled against present practice is that preoccupation with research, especially the writing of a dissertation on a restricted topic, is narrowing. It involves, it is said, the learning of more and more about less and less, whereas the need of prospective teachers is breadth of knowledge and ability to organize, synthesize, and criticize a wide range of ideas. This position has been expressed persuasively and in detail by Howard Mumford Jones in his book, *Education and World Tragedy*,[3] in which he proposes drastic reorganization of the conventional graduate college into two units, one an institute of research for the training of research workers and the other a graduate college for the training of teachers. Others, while favoring no such drastic solution,

[3] Cambridge, 1946. For discussion of various aspects of this issue, see also T. C. Blegen and R. M. Cooper (editors), *The Preparation of College Teachers*, American Council on Education, July 1950; President's Commission on Higher Education, *Higher Education for American Democracy*, Vol. I, pp. 84-91 and Vol. IV, pp. 1-26, Washington, U. S. Government Printing Office, 1946; W. S. Gray, "Preparation and In-service Training of College Teachers," *Proceedings of Institute for Administrative Officers of Higher Education*, Vol. 10, 1938; Ruth E. Eckert, *The Preparation of College Teachers*, National Education Association, 1948; Fred J. Kelly, *Toward Better College Teaching*, Washington, U. S. Government Printing office, 1950.

propose increasing attention to the objective of training college teachers which, they feel, is not now being satisfactorily achieved. One of the most forceful expositions of this middle position is a report of a University of Chicago group: "A Statement of Policy and Plans Prepared by the Committee on the Preparation of Teachers."[4]

According to the Chicago report, the role of the college teacher includes five functions: (1) to participate in formulating the educational ends and the curricular structure of his institution, (2) to guide and encourage students in learning something of the nature and use of the essential knowledge and characteristic methods of his teaching field, (3) to engage in research and other types of creative activity, (4) to serve as counselor of students, and (5) to participate as a citizen and especially to assist in interpreting to the community his institution and higher education generally. The substantive training of a college teacher should include a well-balanced general education in the arts and sciences, a command of the broader division of knowledge within which his field of concentration lies, and acquaintance with the full range of basic research methods used in his field.

The Chicago report states that "the college teacher must be essentially an interpreter rather than creator of knowledge. . . . Yet the *interpretation* of knowledge should not be confused with the mere *transmission* of knowledge. . . . The best interpretation and hence the best teaching will seek to bring about the active reconstructing, by both teacher and student, of the processes whereby some present outcome was achieved in the past and further knowledge may be gained in the future. It follows that the interpretations of the college teacher will be most precise and authentic if, as graduate student, he himself made a contribution to understanding and if, as teacher, he remains capable of making further contributions to it. Therefore . . . the college teacher should have training in research of such a character as to give him the experience of making a contribution to understanding. However, because much of the research which has been done by graduate students has been trivial, repetitive, and unilluminating, the Committee further believes that the research training of a prospective teacher should be acquired whenever feasible in connection with a problem of such scope and significance as will lead him to employ a considerable variety of the principles, materials, and techniques of his eventual teaching field."[5] The Chicago report offers two proposals: (1) a seminar in college teaching, and (2) apprentice training, after the completion of the dissertation, at stipends equal to the salaries students might have

[4] Mimeographed, June 14, 1948. Dean F. C. Ward was chairman of the Committee and Professor H. A. Anderson its executive secretary.

[5] Ibid. pp. 10-11.

obtained as instructors elsewhere. The committee is critical of most present part-time teaching assistantships because the student gets little training or supervision and because teaching tends to be a secondary interest during the period of his graduate study.

The main concern for greater attention to the training of college teachers has been expressed not only in words but also in actions. Several universities have established seminars or courses in techniques of college teaching; some have attempted to give close supervision and guidance to teaching assistants; several (notably Harvard and Syracuse) have instituted new doctoral programs in "social science" intended especially for prospective teachers; other universities while retaining the form of the traditional Ph.D., have in fact changed the orientation from research to teacher training; others, while retaining the conventional Ph.D., have undertaken to provide short courses and other educational experiences for college teachers who are already on the job.[6] Several conferences on the subject of training college teachers have been held, and the American Council on Education has evidenced active interest in the subject.

Though a considerable number of educators have criticized the traditional graduate program on the ground that it is not entirely suited to the needs of the prospective college teacher and though many proposals for reform have been made and some acted upon, yet my impression is that a great majority of those concerned with graduate education do not favor substantial departure from conventional practice.

The Association of American Universities in 1948 expressed itself forcibly in favor of retaining the traditional Ph.D. when it adopted a report stating: "We re-affirm our belief that the essential requirements for the Ph.D. degree as they are now in force at the member institutions are in general fundamentally sound. The Ph.D. degree is granted to those students who (1) have mastered a definite field of knowledge so that they are familiar not only with what has been done in the field but as well with its potentialities and opportunities for further advances, (2) have demonstrated capacity to do original and independent scholarly investigations in the field, and (3) have ability to integrate their field of specialization with the larger domains of knowledge and understanding. The training for the Ph.D. degree involves the demonstration that difficult problems can be solved through properly conducted research. . . . Much of the criticism of the present programs for the Ph.D degree has come from those who contend that most of the individuals who receive the degree become college teachers and that the

[6] Cf. Report of the Committee on Graduate Work, "Results Obtained from a Questionnaire Study on the Training of College Teachers," Association of American Universities, *Journal of Proceedings and Addresses*, 1948.

training which they receive is unsuitable for the college teacher. Some of the criticism is based upon superficial examination of the facts and upon failure to recognize the complexities of some of the problems. The thesis that long preoccupation with special knowledge serves to make a man unfit to explain the elementary matters in his own field has yet to be proved nor does the likelihood that this is true appeal to common sense. Teaching is actually an art, the successful practice of which depends on qualifications in addition to knowledge such as a pleasing manner, a good voice, an aptitude for dealing with people, a skill in simple exposition and an ability to distinguish an important point from a detail. However, the training which has shown an individual the danger of easy generalization in one area of scholarship should serve to guide him in all generalization and so make him a safer guide in the classroom.... It must be emphasized that a finished college teacher cannot be produced even by the best program a graduate school might develop. Excellent teaching comes only with experience and continual self-improvement which the individual as well as the institution employing the teacher must recognize. . . . The experience gained in selecting and carrying out a piece of research has inestimable value for the student preparing for an intellectual career, whether as a research scientist, a worker in the social field, or as a college teacher."[7]

Views of Economists

From my inquiries among graduate professors of economics I have concluded that a great majority would agree with the view expressed in the above quotation. When asked: "Do you feel that you have any responsibility to train your doctoral students in the art of teaching?," 55 percent replied in the negative, indicating that the only training should be by example and by general training in written and oral presentation. Another 40 percent thought that their responsibility for teacher training included only the provision of teaching assistantships and informal aid to these assistants. Apparently no one favored formal instruction in pedagogy as part of the doctoral program.[8] From verbal conversations on this point, it was evident that many professors view with horror the possibility that courses in "education" might be given to doctoral candidates. They are adamant in the opinion that if any instruction in pedagogy is to be given it should be done by economics departments, or perhaps by social science divisions, and not by

[7] Report of the Committee on Graduate Work, "The Significance of and Proper Training for the Degree of Doctor of Philosophy," Association of American Universities, *Journal of Proceedings and Addresses*, 1948.

[8] Schedule VII: 59 respondents.

departments of education. On the question of whether the programs of prospective college teachers and prospective research workers should become separate and distinct, the response was an equally clear-cut negative. Only one respondent thought this a good idea, three gave qualified approval, and all the rest were opposed.

Heads of departments of economics in those institutions of higher education which do *not* give graduate work, however, expressed somewhat different views. They were asked: "What is your reaction to the frequent proposal that graduate study should be oriented more largely toward preparation of teachers rather than toward the training of research scholars?" Only 22 percent responded negatively, some of these indicating that training for teaching is secondary to other aspects of graduate education or that there is no conflict between the objectives of training for teaching and for research; 32 percent thought that more emphasis should be given to teacher training, though many of these felt that there was no necessary incompatibility between the two objectives; the remaining 46 percent responded favorably in a way that would indicate support for a considerable increase in the attention given to teacher training, some of these suggesting that the emphasis on research has been greatly overdone.[9]

To summarize, professors in *graduate* departments of economics are overwhelmingly unsympathetic to the idea that the Ph.D. program should be modified substantially in the direction of greater attention to teacher training. On the other hand, many of the heads of *undergraduate* economics departments, which are the principal academic employers of economists, feel that more attention might be given to the training of college teachers.

Some Proposals

My own views of this disputed subject are about in the middle of the various opinions now current. I feel that the essential orientation of the Ph.D. toward research is sound—whether the training is intended for prospective teachers or prospective research workers. As repeatedly suggested in this report, the qualities required for successful teaching are by no means wholly different from those required for effective functioning in other positions which economists are called upon to fill. Knowledge of the subject, scholarly competence, and ability to convey economic ideas are indispensable in virtually all professional work in economics. Nevertheless, just as I believe that many departments of economics should improve their research training, so I think that many should improve their teacher training. I believe this latter could be done without

[9] Schedule XI: 89 respondents.

detracting significantly from the research training and without elaborate reorientation or reorganization of graduate instruction.

In most departments, teacher training occurs in three ways: (1) students observe the teaching of the professors from whom they take courses, (2) students gain experience in oral presentation and discussion, and (3) students are employed as teaching assistants. Improvement is possible in all three of these respects, and certain additional methods are feasible and worth trying.

First, it goes without saying that if students are to learn from the example of their graduate professors, the level of teaching in courses attended by graduate students should be good. Anyone familiar with graduate instruction will concede that improvement is sometimes possible here.

Second, it would surely be desirable to require or encourage students to gain more experience in oral presentation and in discussion. This can be accomplished both within and outside the classroom. I have gained the impression that at many institutions student participation within the classroom and in conferences with faculty members is less than would be desirable. I have also felt that the atmosphere and the traditions of some departments are not congenial to the kind of free informal discussion among graduate students which can be a most fruitful educational experience. Positive steps could be taken toward improvement.

Third, much can be done to transform the work of teaching assistants into a genuine apprenticeship in which the student progresses from less to more responsible functions and throughout which he receives guidance, assistance, and helpful criticism from staff members. Practice in this respect varies greatly among institutions. At the one extreme are the institutions which use no teaching assistants; at the other extreme are those which use assistants extensively but with a minimum of instruction or guidance.

Teaching Assistantships

A fairly persuasive case can be made for the employment of graduate students as teaching assistants. This practice can be defended on grounds of institutional efficiency and of effective graduate education. Graduate students, if properly selected and supervised, can serve usefully in the teaching of undergraduates. The cost of this service can be low—especially when it is considered that the same expenditure provides an alternative to scholarships for graduate students. At the same time, by serving as teaching assistants, graduate students can learn a great deal about economics.

It is true that the system of employing graduate assistants is often

abused. In some institutions, so much of the undergraduate load is carried by inexperienced assistants that undergraduates seldom have contact with mature and experienced professors. In some institutions the assistants are not given adequate guidance and assistance, and are thrust without adequate preparation into responsible and largely unsupervised teaching. Educational atrocities are sometimes committed through careless use of teaching assistants. But the system is not inherently bad if not abused.

The following is an outline of a scheme for using graduate assistants which I believe can be defended on educational grounds—from the point of view both of training college teachers and of providing good undergraduate instruction. The scheme is based on two fundamental principles: (1) that the undergraduate offerings should be arranged so that a major part of the work of each undergraduate student would be under mature full-time staff members, and (2) that no graduate student would be placed in responsible teaching without considerable prior experience under supervision.

Under this scheme, a graduate assistant would begin as an apprentice to a full-time staff member. His duties would be to assist in the preparation of examinations, problems, and teaching materials; to help with clerical work; to conduct classes occasionally—sometimes in the absence of the professor but sometimes also in his presence; to observe the teaching methods of the professor by attending classes regularly. As a result of this relationship, the professor could determine when the student would be ready for more responsible teaching. When this point had arrived, the student might be transferred to a large elementary course of multiple sections. Here he would serve again under the direction of the professor in charge. Through frequent conferences he would participate in the planning and conduct of the course, and would have opportunity to discuss methods of presentation and teaching problems.[10] If the graduate assistant succeeds in this teaching under supervision, he is then ready to be recommended for greater responsibility and independence.[11]

[10] His classes might be visited by the professor-in-charge, possibly by other professors, and also by his contemporaries. In my opinion, the inhibition in American higher education against the visitation of classes to observe teaching is unfortunate. Every teacher could afford to learn from his colleagues and superiors about the weaknesses and strengths of his own teaching techniques. Yet teachers are shut off from this source of criticism by the taboo that such visitation is a violation of privacy. However, there is considerable difference of opinion on this point.

[11] A special problem exists in those institutions which are so located that many of their graduate students serve as part-time teachers in nearby colleges. This is especially true of institutions located in large cities. It is possible that some kind of formal cooperative relation between the graduate department and the employing colleges would be helpful. There are obvious difficulties in this, but it would offer distinct advantages to all concerned if the administrative details could be mastered.

The educational values of teaching assistantships are sufficient to warrant giving this experience to as many students as can be done without seriously impairing the quality of undergraduate instruction. Some universities are trying to give every doctoral candidate some teaching experience; this policy has much to commend it. In the preceding chapter it was pointed out that *research* assistantships are also commendable. Of course, the question arises as to whether students should have *both* research and teaching experience during their graduate careers. I am inclined to answer affirmatively, though I recognize the difficulties and the probability that this would lengthen the period of graduate study for many students. I have serious doubts as to whether it is desirable for a graduate student to proceed through his entire graduate career without some practical experience in teaching and/or research. Therefore, I have doubt as to the wisdom, in many cases, of granting scholarships for which no services are required—except during the period when the student is engaged in writing a dissertation.

Seminar in College Teaching

Along with this apprenticeship scheme, a seminar might be offered on college teaching generally or specifically on the teaching of economics. The purpose of such a seminar might be to acquaint the student with educational objectives, teaching methods, curricular problems, student guidance, responsibilities of faculty members, etc. Such a seminar would be, not a substitute for other work, but an addition. This is the same as saying that it should carry no credit. It might be provided as a service to those students who wish to prepare specifically for teaching, or it might be required of those students who are serving as teaching assistants. On the question of whether the seminar should be given by the department of economics, by a division of social sciences, or by the graduate college, I do not have strong views. Generally, I should prefer that it be given by the department. Such a seminar might, over a period of time, contribute significantly to pedagogy and exert a constructive influence upon quality of economic teaching and upon the character of courses in the field.

My recommendation of the seminar in the teaching of economics at the college level is based partly on the belief that we know little, systematically, about pedagogy in economics at the college level. So far as I can learn, we are vague about the objectives of college courses in economics. We have little reliable information about content, methods of instruction, or personal qualities of teachers as related to the attainment of whatever objectives may be decided upon. I should hope that if a few active and continuing seminars in the college teaching of eco-

interested in the subject, results of importance to the whole profession might be achieved.

In-service Training

A major issue in the training of college teachers concerns the division of responsibility between the graduate departments in which students are trained and the institutions which later employ them as teachers. Opinion on this question is apparently divided. Some believe that virtually the entire responsibility should be assumed by the graduate departments, and that students who receive the Ph.D. should be finished teachers ready to take on a variety of courses independently and without further guidance. Others believe that graduate departments should assume no responsibility beyond training students in subject matter and research technique, and that it is up to employing institutions to induct them into the job of college teaching in all of its aspects. Others, among them myself, feel that there should be a division of responsibility—that it is unreasonable to expect the new Ph.D. to be a fully-trained and seasoned teacher, yet that he should have had the kind of experiences which would enable him to develop rapidly into a successful teacher (at least within the limits of his talents). At the same time, the employing institution should provide in-service training and supervision which would lead him to recognize and overcome weaknesses and bring out his potentialities. This viewpoint was reported by a majority of the heads of economics departments (in institutions not offering graduate work). The comments of these department heads were as follows (in the order of frequency):

Employing institutions should provide orientation and inservice training programs to clarify objectives and general policies, to help young teachers to grow, and to assist with problems.

Graduate departments should acquaint students with content, method, and philosophy.

Graduate departments should give more attention to teacher training.

Graduate departments should provide supervised teaching experience.

Employing institutions—especially small ones—are not qualified and have no facilities for teacher training.

Graduate departments should turn out competent teachers.

Graduate schools should appraise their candidates more carefully and be more scrupulous in their recommendations.

Employing institutions should give financial aid to young teachers who are trying to complete doctorates.

Teachers are born, not made.

Teachers are self-trained.

Employing institutions have difficulty with in-service training because of the tradition against class visitation or supervision.

Teacher-training "courses" should be resisted—especially if they are to be given by departments of education.

The provision of in-service training for young college teachers is a delicate task requiring a good deal of tact and friendly interest. It can be accomplished most easily and naturally if the new teacher begins his work in a course having multiple sections supervised by a mature professor who is interested in developing good teachers. Another device that may be useful in some institutions would be a seminar or discussion group on teaching problems to be attended by young teachers and led by a mature professor vitally interested in the subject. Orientation literature may be developed. An outstanding example of this is a pamphlet *You and Your Students,* which has been published for its staff by the Massachusetts Institute of Technology.[12] Still another possibility is regional meetings or short courses on teaching problems. These might be conducted by universities to serve the teachers of their areas. The usual professional meetings, while sometimes including discussions of educational problems, do not fully meet this need.

Conclusion

I should reiterate that the kind of approach to the problem of teacher training which I am suggesting does not involve significant reorientation of the Ph.D. program. I believe, and I think most economists concur, that the Ph.D. should continue to be oriented primarily toward research and scholarship in economics. This is the most important aspect of the training of *economists* regardless of their career objectives. In the long run, the best teachers will be produced by this method rather than by a program more specifically related to teacher training. In particular, I would reject the view that prospective teachers should write a kind of doctoral dissertation different from that selected by prospective research scholars.

In my opinion, the view that research-oriented dissertations are undesirable for prospective teachers is based on confusion as to the meaning of "narrowness" or "breadth." A research topic may be limited in scope, indeed it usually must be so limited, but that does not necessarily mean that work on that topic will have a "narrowing" influence on the student. If the topic is a significant one, the student will be required to know how it fits into the broader body of knowledge to which it is related. In working on it, he will be required to familiarize himself with a wide range of relevant literature and sources, he will become acquainted with the tools and methods of research, he will discover cognate problems for further research, and he will gain a "feeling" for

[12] This pamphlet was prepared by a faculty committee under the chairmanship of Professor R. D. Evans.

the process by which research is conducted. These are broadening, not narrowing, experiences, even though the subject itself is specific and limited.

It is true some research topics, even important ones, may not be suitable for doctoral dissertations because they may not have sufficient educational potentialities. But merely because some research topics are unsuitable should not justify condemning all research as "narrowing."

There is also another confusion. Those who regard dissertations based on research as "narrowing" tacitly assume that the doctorate represents the termination of the educational process, and that the dissertation will be the final intellectual effort of the student. Unfortunately this is so in many cases; yet, the entire graduate program can hardly be organized on the assumption that this will be so. The doctoral dissertation is intended to be but one of many studies to be conducted during a long lifetime of intellectual endeavor. It is intended to prepare and encourage students for future scholarly work. To say that this one first effort is narrowing is to overlook the fact that it is intended to be but one small part of the student's total intellectual life.

Chapter 11

TIME SPAN OF GRADUATE STUDY

This chapter is concerned with the length of time involved in the education of economists. Data are presented on the periods of study prescribed for advanced degrees in economics, and on the amount of time students actually spend in meeting the requirements for these degrees.

Credit Requirements

In most institutions, the minimal requirements for the master's degree in economics are stated in terms of a number of credit hours which might be earned by a student in one academic year of resident study. In universities on a semester basis, the number is usually around 24 hours plus a thesis or, if credit is given for the thesis, around 30 hours.[1] Many institutions require that at least a certain major fraction of these hours must be taken in economics. Most require also that the student achieve at least a certain minimal grade average (usually "B") or that only a limited amount of credit will be counted for any course in which the grade is lower than "B."

Similarly, the Ph.D. in economics is usually defined in terms of a course of study which can be completed in two academic years (including the year of study for the master's degree) plus a dissertation. The dissertation is thought of as the equivalent of one year's work; hence, the entire program for the Ph.D. is formally regarded as a three-year course. In some institutions, the requirement for the Ph.D. is stated in terms of a certain number of credit hours or courses, passed with at least minimal grades (usually "B") and a dissertation. In others, there is no formal requirement except the passing of comprehensive examinations and the completion of the dissertation. Even in these institutions, however, the program is conceived as a three-year course.

There is little criticism of these formal requirements for the master's degree and the Ph.D., and little disposition toward change—though a few professors think that some of their colleagues are a bit lax in their standards for grading graduate students.

Residence Requirements

Most institutions do not require students to be in residence during the entire period when they are earning the credits and writing the theses

[1] In institutions on a quarter system, the number of hours is adjusted accordingly.

demanded for the advanced degrees.[2] In practically all institutions, the minimal residence requirement for the master's degree is one academic year. Once this requirement is met, many permit the student to write his thesis *in absentia,* and some permit him to take limited amounts of extension or correspondence courses or to engage in independent study for credit while not in residence. Residence requirements for the Ph.D. are less standardized. Most institutions require two or three years. A few permit students to obtain credit for independent study *in absentia,* and all allow the dissertation to be written *in absentia,* once the residence requirements are met. There is apparently little criticism of existing *formal* residence requirements (except for provision about work *in absentia*) and no significant effort is being made to change them.

The important issues regarding residence relate not to the formal requirements, which are generally accepted as reasonable, but to the amount of time which candidates actually spend in earning advanced degrees in economics. This subject will be considered in the remainder of this chapter.

Actual Residence

Table 34 shows the percentage distribution of respondent graduate students in economics by length of period of residence between selected points in their graduate careers. The table also shows the mean and median periods of residence. According to these figures, there is considerable dispersion in length of residence. For the master's degree, residence varied from less than one year to 4 years, and for the Ph.D. from 2 to 5 or more years. The great majority of master's degrees were received, however, after one or two years of residence (column 1); the majority of preliminary exams were passed after two or three years of residence (column 4); and the majority of Ph.D's were received after three or four years of residence. As indicated in the table, the mean period of residence prior to the master's degree was 1.5 years, prior to the preliminary examination 2.5 to 2.9 years, and prior to the Ph.D. 3.7 years.[3]

The formal residence requirements of most institutions would call

[2] I did not explore the complicated question of the treatment of students who transfer from one institution to another. Hence, the discussion of residence refers to those students who do all their graduate work at one institution.

[3] A study of the actual periods of residence of graduate students who received the Ph.D. from the University of Minnesota indicated that those who received Ph.D.'s in economics during the pre-war years 1936-37 to 1940-41 had been in residence at Minnesota on the average for 13 quarters, and that those receiving degrees during 1941-42 to 1947-48 had been in residence on the average 14 quarters. Figures for other fields indicated that this average was about typical for all the departments of the University. University of Minnesota, Graduate School, *Graduate Faculty News Letter,* Dec. 9, 1949 (Mimeographed).

TABLE 34.—RESIDENCE OF GRADUATE STUDENTS BETWEEN SELECTED POINTS IN GRADUATE CAREERS[a]

Approximate number of years in actual residence	Bachelor's to master's	Master's to preliminary examination	Preliminary to Ph.D.	Bachelor's to preliminary	Bachelor's to Ph.D.

½	4%	11		2%	
1	42	15		—	
1½	10	29		23	
2	36	13		26	
2½	6	2		15	
3	1	2		19	
4	1	—		13	
5 or more	—	—		2	
Total	100	100		100	
Mean	1.5 years	1.0 year		2.5 years	

[a] These data were derived from responses to a request for "dates in residence." The data presented are approximate because many respondents did not make clear whether they had attended summer sessions or whether they had been in residence during the whole of any specified academic year. A "year" should be interpreted, therefore, loosely as one academic year or as one academic year plus one summer. No differentiation was made between full-time residence and residence during which the student carried less than a full-time load.

[b] Schedule X: 218 respondents. Comparison of data for the 1939–40 group and the 1949–50 group revealed no significant differences.

[c] Schedule IX: 140 respondents.

for one year prior to the master's degree and two or three years prior to the Ph.D. Evidently, then, actual residence is significantly longer than the requirement. This is accounted for in part by the fact that many students are engaged in part-time work during their residence, but it is also due to the inability of many students to prepare themselves in the minimal allotted time.

Most graduate professors apparently are well-satisfied with the actual periods which their students spend in residence—despite the fact that it is typically longer than the minimal requirements. When asked to express their opinions on the amount of time candidates typically spend in residence (as distinct from formal residence requirements), their replies were as follows:

	Master's candidates[4]	*Ph.D. candidates*[5]
too long	10%	14%
too short	2	12
about right	77	63
uncertain	6	10
no answer	5	1
Total	100	100

In commenting on this subject, several respondents indicated that the residence of doctoral candidates is too short in that too many dissertations are prepared *in absentia.*

Elapsed Time

A subject on which there is somewhat greater concern, and in my opinion should be even more concern, is the amount of time that elapses between the beginning and the completion of graduate work. Table 35 presents data on this subject for respondent graduate students, of whom some were in residence in 1951-52 and others received degrees earlier. "Elapsed time" is defined as the length of time between two points in the student's academic career. During part of this time he may not have been engaged in graduate study at all, or he may have been studying only on a part-time basis. Therefore, "elapsed time" is not a measure of the time actually spent in climbing from one point to another on the ladder, but the interval that occurs between these points for whatever reason. Elapsed time is significant in that it indicates the amount of delay, lost motion, uncertainty about career objectives, etc., which, together with the time actually spent in study, determines the age at which candidates reach various points on the ladder. As shown in table 35, the range of elapsed time between each of the successive points is surprisingly great. A substantial minority of students pass from one step to another in about the time theoretically required, namely, one year from bachelor's to master's, one year from master's to preliminary, and one year from preliminary to Ph.D. But there are few students who go the entire distance from bachelor's to Ph.D. in the theoretical three years. A majority take 10 years or more.

[4] Schedule IV: 61 respondents.

[5] Schedule VII: 59 respondents.

TABLE 35.—ELAPSED TIME BETWEEN SELECTED POINTS IN GRADUATE CAREERS

Approximate number of years of time interval	Bachelor's to master's	Master's to preliminary examination	Preliminary to Ph.D.	Bachelor's to preliminary	Bachelor's to Ph.D.

[a] Schedule X: 218 respondents.
[b] Schedule IX: 140 respondents.

The same phenomenon is also illustrated by data on the ages at which graduate students reach each point on the ladder. These are shown in table 36. The average age at the time of receiving the master's degree was about 27 years, and the average age at receipt of the Ph.D. about 32 years.

These figures on both elapsed time and age are confirmed by other

studies. A University of Minnesota study[6] indicated that the elapsed time between the bachelor's and the Ph.D. for economics students at that institution was about 8 or 9 years and the average age at time of receiving the Ph.D. about 33 or 34 years. These figures were somewhat higher than the average for students in other fields. A study of economics students at Columbia University[7] revealed the following average intervals of elapsed time:

A.B. to M.A.	3.0 years
A.B. to Orals	5.8
A.B. to Ph.D.	10.6
M.A. to Orals	2.8
M.A. to Ph.D.	7.8
Orals to Ph.D.	4.1

TABLE 36.—AGE AT SELECTED POINTS IN GRADUATE CAREERS

	Age of former graduate students who received advanced degrees in 1939–40 or 1949–50[a]			Age of graduate students in residence 1951–52[b]	
	At bachelor's	At master's	At Ph.D.	At bachelor's	At master's

Mean[c]	23.0 years	26.6 years	31.9 years	24.0 years	27.4 years

[a] Schedule X: 218 respondents.
[b] Schedule IX: 140 respondents.
[c] The average increase in age between various points does not agree precisely with elapsed time as shown in table 35 because of difficulties of interpreting data on elapsed time. The data on ages are more reliable.

A tabulation by Dr. Lewis A. Froman covering the period 1929-1940 indicated that the average elapsed time between bachelor's and master's varied for the several years from 2.3 to 3.0 years; between master's and doctor's from 4.2 to 5.5 years; and between bachelor's

[6] *Graduate Faculty New Letter, op. cit.*

[7] J. W. Angell, *Occupations and Salaries of Former Graduate Students* (mimeographed), June 20, 1951. This study covered students who received degrees during the period 1931-1950. The averages do not include a few extreme cases.

and doctor's from 8.4 to 9.9 years.[8] Professor George J. Stigler has presented data on elapsed time between the B.A. and Ph.D. for students in various fields at Columbia and Harvard covering selected years between 1900 an 1940. These figures indicate an average interval in 1940 of about 9 years at Harvard and 13 years at Columbia for students in the social sciences.[9]

Although World War II undoubtedly had an influence in lengthening the average elapsed time, the effect was apparently not pronounced. Factors causing delay were compensated in part by the veteran's benefits which encourage early completion of graduate work. Aside from certain irregularities caused by the war, there has been no pronounced trend in the average elapsed time—at least since 1930. Professor Stigler's data indicate, however, that the average interval between B.A. and Ph.D. at the two institutions he studied was considerably less before World War I than since.

TABLE 37.—SUMMARY OF DATA ON RESIDENCE AND ELAPSED TIME (arithmetic means expressed in years)[a]

	Theoretical time	Actual residence	Elapsed time	Age at completion of step
From bachelor's to master's	1			
Former graduate students		1.5	3.3	26.6
Graduate students in residence 1951–52		1.5	3.5	27.4
From master's to preliminary	1			
Former graduate students		1.5	3.6

Summary of Data

The data on residence and elapsed time are summarized in table 37. This table shows the theoretical time required between various points in the graduate program, the actual average periods of residence, the average elapsed time, and the average ages of candidates at the completion of each step. As the table indicates, the period of actual residence exceeds the theoretical time. The average residence for the master's degree is 1.5 years or one-half year more than the theoretical time. This is accounted for in part by the fact that at some institutions the master's degree is awarded after successful completion of the preliminary examination. However, the difference is due mainly to the fact that many students are in residence for more than one year before completing the requirements for the master's degree. This has become the typical situation at many institutions. The residence from master's to preliminary for former students also exceeded the theoretical one year, but for the 1951-52 group, the average was equal to one year. The residence from the preliminary to the Ph.D. is slightly less than the theoretical one year. This is due to the fact that many students write all or part of their dissertations *in absentia*. The fact that the average is so close to one year (and that many dissertations are written partly or wholly *in absentia*) suggests that the task of preparing a dissertation ordinarily requires substantially more than one year. Altogether, the average residence from the bachelor's to the Ph.D. is 3.7 years or 0.7 of a year in excess of the theoretical 3. When it is considered that the average residence is 3.7 years and that many students do considerable work *in absentia*, it must be concluded that the total *work* time required for a Ph.D. is probably on the average more than 4 years. The elapsed time exceeds the theoretical time by threefold.

Concluding Comments

The question posed by the above facts is whether the elapsed time—especially for the Ph.D.—is too long. A substantial number of graduate professors believe that it is; on the other hand, a somewhat larger number do not find the elapsed time excessive. The responses on the elapsed time for the Ph.D. were as follows:[10]

too long	34%
too short	3
about right	41
uncertain	7
no answer	15
Total	100

[10] Schedule VII: 59 respondents.

The arguments favoring the long period before completion of graduate work pertain to maturity and experience. It is said that students gain more from graduate study and perform more satisfactorily if they have substantial work experience and maturity. This they cannot have if they pursue graduate study uninterruptedly after college. There is undoubted validity in this argument. If one were to outline the ideal sequence of events in the life of a doctoral candidate, one might well prescribe some work experience prior to completion of the degree. In the preceding two chapters, I have already pointed out the advantage of experience in research and teaching and have recommended that as many students as possible serve as research and teaching apprentices. In many cases, it might be desirable for some of this experience to be obtained on the job away from graduate school. But there is a genuine question as to how much experience and consequent delay before taking the Ph.D. is necessary or desirable—all things considered.

The answer to this question depends in part on one's conception of the Ph.D. If the Ph.D. is to be reserved only for mature persons who have been seasoned by years of practical experience, then the long period of gestation is justified. This concept of the Ph.D. was undoubtedly encouraged during the period when the degree was becoming a union card for college teaching and when, therefore, the graduate student body contained many older college teachers bent on acquiring the approved credentials of their profession. If, on the other hand, the Ph.D. is regarded not as something to be awarded in middle life after some of the most productive years have passed, but as something to be given to a young person who has mastered the basic knowledge and techniques of economics and who shows ability and promise, then the argument for the long period becomes much less persuasive. I lean strongly toward the latter concept of the degree. I feel that although a year or two of experience is undoubtedly most useful, further delay is usually undesirable and in many cases disastrous.

The explanation of the long period of elapsed time is almost always one or more of the following (aside from military service): (1) delay in the choice of a career, (2) inadequate prior preparation for graduate study, (3) financial necessity, (4) procrastination, and (5) overly ambitious dissertations. No one of these can be strongly defended.[11] I have heard of few candidates who deliberately delayed the Ph.D. for any extensive period in order to gain experience—or even who were advised to do so.

[11] A critic suggests that another reason for slowness is the tendency for the adviser (and the rest of the faculty) to insist that the student take all courses that would aid his examination performance before permitting him to stand for his preliminary examination. He adds "It's not all the student's fault. The preliminary should be taken as early as possible—after only the basic minimum of course work is taken."

It seems to me that the frequent delay in the choice of a career is due partly to faulty recruitment policies. As pointed out in Chapter 6 efforts should be made to achieve earlier recruitment and selection of students who are fitted to become professional economists. It is true that not every student can be expected to find himself before the end of his undergraduate years. Yet there is obviously much less uncertainty in the case of those who enter law, medicine, architecture, engineering, or chemistry than is true of those entering economics. It is up to the economic profession to do a better job of recruitment and selection of students for graduate study.

The problem of inadequate prior preparation has been discussed in Chapter 6. That this is a frequent cause of delay in the completion of a doctorate can hardly be doubted.

The financial problem is always present and will undoubtedly cause undesirable delay for many students. Yet this problem is less urgent for younger students whose family obligations are likely to be minimal than for older students. Therefore, better and earlier recruitment and selection will help in this respect. Other partial solutions are: (1) more funds for financial support of graduate students and (2) use of existing funds to see fewer students through to the degree—rather than more students only through the preliminary examination.

The frequent practice of writing dissertations *in absentia* has multiple disadvantages. The dissertation lacks adequate supervision and the project tends to be pursued as a secondary chore added to a regular job. Under these conditions the student can do justice neither to his job nor his dissertation. As a result frustrations develop which dim the creative spark not only for the immediate project but also for future scholarly work. The situation is even worse for those students whose course work is interrupted by financial necessity. Those who receive the degree after intermittent periods of residence have gained something less than those who have been able to pursue an integrated plan of study without interruption. It is noteworthy that the frustrations and divided responsibilities resulting from the delay and the work *in absentia* occur during the student's most productive years—namely, during the third and fourth decades of his life.

Little need be said about procrastination as a cause of delay. It is surely of frequent occurrence. Graduate advisers should be watchful and should press those students to finish who show signs of putting things off unnecessarily.

The overly-ambitious dissertation is a frequent cause of delay. This again raises the question of the nature and purpose of the dissertation. This has been discussed in Chapters 4 and 9.

The basic issue is this: should the dissertation be a *magnum opus*

which represents an important and extensive contribution to the field? Or should it be a piece of research, suited to the abilities of a young scholar, which will acquaint him with subject matter and technique and will provide a test of his ability to carry on more advanced scholarly work in the future? My judgment leans to the latter alternative. I believe that the scale and scope of a dissertation should be such that a student could be reasonably expected to complete it in a year (or at most two years) of concentrated work. The dissertation should not be thought of as a final scholarly product representing the most advanced work of which the student will ever be capable, but rather as a first major effort which may be developed further in later years—or which may be the first of a long series of research enterprises to be conducted by the student over his working lifetime.

The long time-period of most graduate careers is a significant cause of mortality among students. As time goes on without completion of the degree, students become immersed in their work, acquire increasing financial responsibilities, and become discouraged. The result is hundreds, perhaps thousands of partly finished doctorates, and a profession in which many of the practitioners have not had adequate academic training or the discipline and experience of carrying on a solid piece of independent research. I would not argue that in all cases this is disastrous or even undesirable. But the profession, collectively and individually, would be more productive and more competent if a greater proportion of the practitioners had been persuaded, or had been able, to find a way to complete their graduate programs.

Chapter 12

THE GRADUATE DEPARTMENT OF ECONOMICS

In this chapter, graduate education in economics will be considered from the point of view of the qualities and characteristics of the departments in which it occurs. I shall raise issues and offer tentative suggestions regarding the staff, facilities, organization, and opportunities afforded by graduate departments of economics. Whereas earlier chapters have dealt with various aspects of the educational process, this one will be concerned with the departments in which the process takes place.

I approach this subject with extreme diffidence because I am fully conscious of the fact that there is by no means a necessary correlation between the physical characteristics of a department of economics and the quality of the education conducted therein. A large budget, a distinguished staff, and the most complete facilities do not *necessarily* make a good department. While Mark Hopkins on the end of a log or Socrates conversing in the public square may not represent the ideal educational situation for all purposes, yet excellent education can sometimes be had with minimal staff and facilities. Nevertheless, my discussions, observation, and thinking on the problem all have led to the conclusion that the nature of the department does make a difference and that substantial costs are involved in providing graduate education of high quality.

A Graduate Department

In all but a handful of universities undergraduate and graduate instruction in economics are closely associated. The same staff and the same physical facilities are utilized for both purposes. This arrangement is advantageous in terms of cost. In addition, it offers the positive advantage of providing opportunities for graduate students to become apprentice teachers. In many institutions, however, there are problems involved in the relationship between the graduate and undergraduate phases of instruction in economics. In some, the emphasis is on undergraduate instruction and the graduate department is merely an incidental appendage which supplies a few assistant teachers and occupies some marginal time of the regular staff. In others, the emphasis is upon graduate instruction and research and the undergraduate part of the program is neglected. In some of these latter the alumni have complained bitterly that the undergraduate student has become the forgotten man of higher education.

This is not the place to consider these large issues. It is worth noting, however, that there are important differences between undergraduate and true graduate work—differences in content, in objectives, and in spirit. Graduate work exists for the purpose of training men to become scholars. The students are relatively mature persons who have chosen their careers and are ready to engage in serious specialized study. They need opportunity for independent creative work of a type that is congenial to their interests and appropriate to their maturity. They need to break away from undergraduate ways and attitudes. This clearly calls for a fairly distinct separation of the graduate from the undergraduate program. There is a real question as to whether adequate graduate instruction can be offered in institutions where it can be only an incidental appendage to an undergraduate program.

Where graduate instruction is given, staff time should be specifically allocated to this activity. There is need for the creation of an environment, a student body, a set of courses, a set of practices, and perhaps some facilities which are uniquely *graduate* and which together can be identified as a graduate program. At some institutions now offering advanced degrees (or planning to offer such degrees) these conditions do not prevail. While these institutions may turn out many good students, there is a serious question if they are providing as good an environment as they should for the development of these students.

Any institution offering graduate work should allot a distinguishable and fairly definite amount of staff-time, courses, funds, and facilities to the graduate program. These things, together, might be thought of as the *graduate department of economics*.[1] I do not mean to imply by this that the graduate department should necessarily be organized as a separate administrative unit, or that its staff members devote themselves exclusively to graduate work. I mean only that there should be an identifiable graduate program sufficiently distinguishable from the undergraduate program to have its own institutional "personality" and its own *esprit de corps*. In the remainder of this chapter, I shall consider the question of what characteristics and qualities such a "graduate department" should have.

Graduate Courses

In general, courses for graduate students should be operated separately from those for undergraduates. While I should not wish to carry

[1] In most universities, the graduate and undergraduate parts of economics departments are at least conceptually distinguishable in that the former is a part of the graduate college and the latter a part of the liberal arts college. I am suggesting that they should be actually distinguishable.

this recommendation to the extreme of suggesting that graduate students should never be permitted to take undergraduate courses or undergraduate students graduate courses, yet on the whole it seems fairly clear that graduate work should involve a break with undergraduate standards, methods, objectives, and attitudes. One of the best ways of making this break is to conduct separate classes of graduate caliber.

The mere provision of separate classes is, however, no guarantee that the desired kind and level of instruction will be achieved in graduate courses. Many professors have reported that they thought the standards in graduate courses were lower than those in undergraduate courses. In undergraduate courses, there is a kind of impersonality, spirit of competition, and definiteness of subject matter which makes for rigor and objectivity in the evaluation of students. In graduate courses, small numbers, personal acquaintance with students, desire to maintain enrollments, and difficulty of applying objective standards all militate against rigor and high standards. It is said that sometimes an "A" or "B" in an undergraduate course actually means a higher level of accomplishment than the same grade in a graduate course. Thus, the suggestion that graduate students should on the whole be taught separately is based on the assumption that the graduate courses would be more rigorous and demanding than corresponding undergraduate courses.

A Ph.D. program of the type suggested here (conducted separately from the undergraduate program) would involve a substantial staff load. It would require the offering of no less than 16 graduate courses and seminars of semester length.[2] These would include perhaps three or four courses in economic theory, one in history of economic thought, two in economic history, two in statistics, and at least seven or eight in other fields. If any considerable range of choices were to be permitted, even more courses would be necessary. But the graduate staff load also includes research and the supervision of theses. This part of the load should be specifically included as part of the official duties of staff members. These activities should not be considered merely extra chores to occupy spare time. Many department heads and graduate deans with whom I discussed these matters feel that staff members should be allotted time for research and for supervision of theses as part of their official teaching load. They feel that the active supervision of 5 or 6 theses should be considered the equivalent of one course. Altogether, these calculations suggest that the provision of a genuine graduate program is a very expensive undertaking in terms of staff requirements.

[2] Perhaps only 8 courses and seminars if only the master's degree is awarded.

Staff

The most important resource of any graduate department of e nomics is, of course, the staff. This raises the issue as to what ough be the characteristics of such a staff, both individually and collectiv

The first question is this: Ought there to be certain minimal sta ards for eligibility of a staff member for graduate teaching in e nomics? Some universities try to set formal standards for admissior faculty members to status in the graduate college. These standards clude degrees, experience, publications, etc. I doubt the efficacy of th standards—at least when they are administered by committees dra from many fields. The standards tend to be expressed in terms degrees, experience, seniority, and number of publications rather tl ability to lead graduate students toward professional competer Unquestionably degrees and experience are desirable. But I doubt t this condition should be applied to *every* member of a graduate st I even question the frequently stated proposition that *every* mem of a graduate staff should have had research experience or should actively engaged in research. It seems to me that the standards fo graduate staff should be applied not to every individual but rathe the entire staff viewed as a group organized to achieve certain p poses. Such a staff might well include individuals who would not m some of the more conventional academic standards.

As we look at the staff as a whole, however, we *can* say that it sho meet certain minimal standards. It should be composed largely persons of maturity, experience, scholarly accomplishment, and *c rently* active research interests. It should also contain a suffici number of well-known and distinguished scholars to give the dep ment status in the eyes of the profession-at-large. Without this cannot give its students confidence that they are studying with mer stature, it cannot give these students support in their later professio careers, and its degrees will be of inferior value in the labor market

Diversity of Staff

The staff should have *diversity* with respect to (1) substantive fi of specialization, (2) theoretical vs. empirical interests, (3) scient vs. policy interests, and (4) academic vs. practical experience. I s comment briefly on each of these aspects of diversity.

First, a sufficient number of substantive fields should be represen by staff members of graduate caliber to enable students to obt authoritative training in (1) the common core areas of econo theory, economic history, history of economic thought, and statist and (2) in at least three or four other major areas of economics.[3]

[3] If only the master's degree is awarded, the number of areas outside the core need at a minimum, only one or two.

view of the importance of economic theory and the wide range of this field, it is possible that more than one staff member in this area would be essential.[4] It is not necessary or desirable, however, that every specialty within economics be represented. The attempt to do so may detract from rather than enhance the quality of the staff. Moreover, it is entirely legitimate for departments to concentrate more heavily in those fields in which they are able to achieve distinction. But such specialization should not be achieved at the expense of inadequate coverage of the core fields and of a sufficient number of other fields to permit breadth of training. In any case, good departments will be more than a collection of technicians and specialists. They will contain men of broad interests and philosophical predilections.

Second, the staff should contain persons whose interests are primarily theoretical, some whose interests are primarily empirical, and others who combine these two approaches. Many existing departments have not achieved balance in this respect. Some are composed almost exclusively of staff members interested in theory, others (fewer in number) are composed almost solely of men whose interests are primarily empirical. I believe that in many departments steps should be taken, in their long-run planning, to correct these imbalances.

Third, any graduate staff should include persons who are interested in the practical application of economics to problems of public and private policy, but at the same time should include persons who approach economics from the point of view of pure science. I believe that considerable imbalance exists in many departments in this respect.

Fourth, any graduate staff should contain persons who have had practical experience in government *and* persons who have had practical experience in business, labor organizations, etc. While it is not necessary to include some staff members who have "carried a precinct or met a payroll," it is desirable to include persons who look at economics from the perspective of important practical affairs of which they have intimate knowledge. Fortunately, the number of academic economists who have had such experience is much larger today than it was a generation ago. This has been one of the contributions to our profession of the New Deal and of World War II. There is also an increasing tendency for academic economists to carry on part-time consulting and other professional activities in government and business while retaining their university connections. Within limits this is wholesome. But it is a practice fraught with potential abuses. It has been reported that some staff members devote so much time to outside activities that they do not give adequate attention to their teaching and are unable to give time to students. Also, it is said that some staff members devote so

[4] It would be desirable for all staff members to be conversant with theory.

much of their energy to programmatic and *ad hoc* research connected with their consulting functions that they no longer engage in fundamental research designed to advance basic knowledge in the field. This problem is said to be even more serious because the heaviest demands from the outside are for the services of some of our most distinguished and capable economists. It has even been said that whole departments are partially undermined by the outside pressures on their staff members. In my judgment this is a serious problem for the entire profession. While outside work is undoubtedly valuable, it should not become so great a preoccupation as to impair the educational and research programs of whole departments. The problem has become serious partly because the services of economists have been in great demand—and because academic economists have felt a responsibility to serve when they would help. A contributing factor has been the low salary scales in universities which have encouraged economists to take opportunities for extra income even when their intellectual interests might have dictated otherwise. These low academic salaries, which are often below the outside competitive market for economists, are explained partly by the necessity of keeping salaries in line with those of professors in fields having fewer alternative opportunities. One wonders if universities might not be wise, from the long-run social point of view, to pay salaries nearer to the competitive level for persons whose outside market value exceeds their academic salaries. At any rate, the objective is to build staffs in which there is reasonable contact with the outside world and thus to bring authentic knowledge of worldly issues to teaching and research in economics.

In the above discussion I do not mean to imply that diversity should take precedence over all other goals in building a graduate economics faculty. Excessive preoccupation with diversity would almost surely result in mediocrity. In the interests of balancing up the team, more competent scholars would often be passed over in favor of second-rate men. Nevertheless, the need for diversity cannot be wholly ignored in staff policy. It is *one* important factor, though not the only one.

In discussing diversity, one is tempted to add a fifth respect in which a graduate staff should be diversified, namely, ideological orientation. It can be argued (1) that the safest antidote to ideological bias is a staff which includes persons having a variety of viewpoints, and (2) that students should be under the tutelage of a group of able persons representing a wide range of ideological positions and should be free to develop their own views in an *environment* which is ideologically neutral. But there are grave dangers in too meticulous concern about "balance" in this respect, especially when this involves weighing ideological considerations in the appointment of individual staff mem-

bers. It would be intolerable if individual academic appointments were made on the basis of applicants' political views rather than on the basis of professional competence. Therefore, it would seem a sounder procedure to achieve ideological diversity as a by-product of diversity with respect to special field, methodological approach, experience, and educational origin rather than by scrutinizing each candidate's beliefs. If genuine diversity in all these other respects is achieved, the probabilities are high that reasonable ideological diversity will also be achieved.

In order to achieve a desirable degree of diversity in the respects mentioned, a graduate department should include a substantial number (at least 6 or 8) staff members who devote substantial amounts of time to graduate teaching and related activities.[5] The program should be arranged so that all students actually have contact with as many of the staff members as possible. For this purpose the prevalence of year-long graduate courses with one professor should be examined with a view to having each student study for shorter periods with a larger number of staff members. This would help to prevent tendencies of students to become disciples of particular professors. Such a relationship usually involves slavish acceptance by the student of the professor's ideas and prevents the student from achieving genuine intellectual independence.

The requirement of diversity calls for the selection of staff from varied sources. There is no place for inbreeding on a graduate faculty of economics. Additional diversity can be obtained by occasionally employing visiting professors who can be useful in introducing new ideas and approaches and also in bringing an outsider's evaluation of existing practices.

Student Body

A graduate student body of small numbers presents certain advantages. With small numbers, it is possible to achieve close personal relations between students and staff members, and to give individual attention to students. A small student body also contributes to friendliness and informality. But smallness in number of students can be overdone. There are important educational advantages, even apart from considerations of cost, to be attained through larger numbers of students. Many professors feel that graduate enrollments of 10 or 20 or 30 are small for the most effective work. Many feel that an optimum graduate enrollment would be perhaps 50 or more.

There are many advantages of larger size: (1) graduate classes (separate from undergraduate classes) can be justified, (2) such classes

[5] The number might be somewhat less if only the master's degree is awarded.

can have enough students (including at least a few very good ones) to permit active group discussion, inter-stimulation, and competition, (3) accurate evaluation of individual students is possible since student accomplishments can be rated in terms of averages and dispersions for large numbers, (4) a kind of impersonal relationship between teachers and students can be established that makes for objectivity in the judgment of students and eases the burden of failing them when it is necessary to do so, (5) larger numbers helps to create an environment in which students learn from each other through informal discussions outside the classroom, (6) with larger numbers there is less concern about maintaining or building enrollments and hence standards can be more rigorously maintained, and (7) a larger student body is likely to be more diverse as to interests, background, geographic origin, etc., and therefore more stimulating. These are important and persuasive considerations. They point toward the conclusion that a graduate program can seldom be conducted effectively with a handful of students and that there are genuine economies of scale to be had in terms not only of cost but of *educational* effectiveness.

At the other extreme numbers can become too large unless staff and facilities can expand proportionately. With too many students, the evils of large classes and excessive impersonality begin to appear. And there may be disadvantages to *very* large size even if a high ratio of staff and facilities to students is maintained.[6] From many discussions with teachers and administrators, I have gathered that graduate classes and seminars of perhaps 5 to 15 students are considered optimal, and that classes which lie very far outside these limits are not likely to meet the educational ideal.

Facilities

The minimal facilities for graduate work include an adequate library[7] and necessary equipment for statistical research. In Chapter 10, I suggested the desirability of a research environment in which various kinds of investigations are being actively pursued. This presupposes some clerical staff and facilities for collecting, tabulating, and analyzing data. Other facilities which are highly desirable include office space for students and common rooms where graduate students and faculty may fraternize. The latter are found effective as a means of stimulating extra-curricular discussion and group morale.

[6] In discussing the relative advantages of various sizes of graduate student bodies, it was assumed that admission standards and student requirements are held constant. If large enrollments are attained by lowering entrance and other requirements, the above arguments do not apply.

[7] See Robert B. Downs, "Leading American Library Collections," *The Library Quarterly*, July 1942.

A Note on Economies of Scale in Graduate Education

As indicated earlier, graduate training is sometimes conducted as an incidental by-product of an undergraduate program: graduate students attend advanced undergraduate classes, carry on independent study, and write theses under the guidance of individual professors for whom the chore of supervision is considered an uncompensated addition to an already full teaching load. Under these conditions, graduate education is virtually without monetary cost. Indeed if it provides a supply of assistant teachers who receive less than the going rate for their services, it may actually show a profit. If, on the other hand, a separate graduate program of the type recommended is to be provided, the cost is substantial.

In this section, I shall try to indicate the order of magnitude of the cost of a minimal graduate program and the relation of the graduate enrollment to this cost. In so doing, I shall make several arbitrary assumptions about the nature of the program and of the student body: (1) that the graduate program is minimal in scope and range of offerings, including only 16 one-semester graduate courses and seminars of which 8 are offered each semester; (2) that the standard teaching load for staff members is three courses; (3) that the average annual salary per staff member is $7,000; (4) that one-half the students are first-year students, all of whom are required to write master's theses, one-quarter are second-year students, and one-quarter are third-year students all of whom are required to write doctoral dissertations; and (5) that the supervision of five theses or dissertations is considered equal to one course in the teaching load of staff members.

The fixed costs will include staff salaries for teaching courses and seminars and for conducting research, and the outlays for a library and other physical facilities. If 8 courses are offered each semester, this will require 2-⅔ staff members (full-time equivalent) at a cost of $18,700. On the assumption that a substantial amount of research should be in progress in a graduate department, I shall suppose that the equivalent of 2 full-time staff members will be assigned to research at a cost of $14,000. Library and other facility costs assignable to the graduate program I have set arbitrarily at $5,000 which is surely a very small figure. The total of these fixed costs is $37,700.

The cost of thesis supervision is variable depending on enrollment. With the distribution of students by classes as assumed, one-fourth of them would be writing a doctoral dissertation each year and another one-fourth would be writing a master's thesis each semester. At any given time, the number of theses and dissertations in progress would be half the number of students. Since five theses or dissertations are

considered equal to one course, 15 of them would require the equivalent of one full-time staff member at $7,000.

With these hypothetical data, the relationship between enrollment and cost would be as shown in table 38. The right-hand column also shows the effect of enrollment on the number of students per class on the assumption that 8 graduate courses are offered each semester.

TABLE 38.—HYPOTHETICAL RELATIONSHIP BETWEEN GRADUATE ENROLLMENT, COST PER YEAR, AND SIZE OF CLASSES

Enrollment	Total fixed cost	Total variable cost	Total cost	Average cost per student	Average number of students per class
10	$37,700	$ 2,333	$40,033	$4,003	1.3
20		4,667	42,367	2,118	2.5
30		7,000	44,700	1,490	3.8
40		9,333	47,033	1,176	5.0
50		11,667	49,367	987	6.3
60		14,000	51,700	862	7.5
70		16,333	54,033	772	8.8
80		18,667	56,367	705	10.0
90		21,000	58,700	652	10.3
100		23,333	61,033	610	12.5
150		35,000	72,700	485	18.8

In view of the large amount of fixed cost (with constant variable cost) in the assumed program, average cost declines sharply as enrollment increases; and in view of the assumption that the number of courses remains constant, the average size of classes increases as enrollment increases. Average classes do not exceed 10 students until the enrollment reaches 80. Therefore, assuming that classes averaging 10 students each are not too large, it could be argued—both on educational and financial grounds—that a desirable enrollment might be 80 or more.

The hypothetical case illustrated in table 38 is arbitrary and artificial. Its only purpose is to illustrate the effect of enrollment on cost and on educational effectiveness. Nevertheless, it casts doubt on the desirability of offering graduate programs when enrollments are very small, or of instituting graduate programs when the prospects of adequate enrollments are slight. When true graduate programs are offered for small numbers of students, the cost is exorbitant and the educational results not necessarily superior.

One may ask: Why do so many departments go into the graduate business on a small scale? The answer, I think, lies basically in the feeling that there is prestige for the university, the department, and the staff in the offering of graduate work. At some universities, depart-

ments have been urged to enter the graduate field by top administrators who hope to achieve greater standing for the entire institution in this way. Other institutions have entered the graduate field in a small way because of a desire to serve students of the immediate area who may not be able to afford to attend a more distant graduate school.

My general judgment on this subject, based on numerous conversations and on the considerations presented above, is that the best environment for graduate work, other things equal, is one in which the number of students exceeds perhaps 40. In cases where only the master's degree is given, the minimum that would seem desirable would be perhaps 30 students.

I have emphasized the disadvantages of small scale operation because that is the problem in most departments. At a few universities, especially since the war, departments of economics have achieved very large graduate enrollments running up to several hundred. A great deal of adverse criticism has been directed toward these departments. It is likely that this criticism was partly justified. Classes have been large, faculty loads of thesis supervision have been heavy, students have encountered difficulty in getting personal attention from professors, many graduate classes have been taught by junior personnel, and facilities have not expanded to accommodate the increased load. At present, however, graduate enrollments in these institutions are apparently declining, and the problem may be disappearing. But if overcrowding in these few departments should persist, stricter limitation of enrollment might be desirable.

Data on Staff, Enrollment, and Costs

One of the questionnaires used in this study requested information on graduate enrollments in economics and on the numbers and salaries of staff officially engaged in graduate instruction and/or research. Because of the difficulty of allocating staff-time between undergraduate and graduate activities, the data obtained were obviously very rough.

Nevertheless, these data point to general conclusions regarding student-staff ratios and instructional costs for graduate education in economics. Altogether, 37 departments, representing all sizes and types of institutions, provided information. The most notable conclusion from these data, as shown in table 39, is the wide variability of graduate departments with respect to enrollments, size of staff, student-staff ratios, and costs per student. The differences in scale of operation as shown by this table are not surprising, but the differences in cost seem so great as to suggest that some departments are wasteful in their expenditures on small numbers of students, and that others are devoting too little resources to graduate instruction. The limiting case of this

TABLE 39.—FREQUENCY DISTRIBUTION OF REPORTING GRADUATE DEPARTMENTS BY NUMBER OF STAFF MEMBERS, STUDENT ENROLLMENTS, STUDENTS PER STAFF MEMBER, STAFF COSTS, AND STAFF COSTS PER STUDENT[a]

Number of staff members officially engaged in graduate instruction and/or research	Number of departments	Number of staff members officially engaged in graduate instruction or research (full-time equivalents)	Number of departments	Number of students in residence 1951–52	Number of departments

[a] Schedule III: 37 institutions provided information on the subject out of 59 respondents.
[b] No information from one respondent.

latter tendency is represented by several institutions (not included in table 39) at which graduate instruction is conducted without any staff or staff costs—in the sense that no separate graduate classes are provided, no staff time is allotted to research, and the supervision of theses is handled by staff members as an extra chore over and above their full undergraduate loads.

There is wide diversity in the relation between student enrollment and staff costs per student. The several departments in any given en-

rollment class vary widely in size of staff and staff costs per student. For example, the staff in the four reporting institutions having enrollments between 30 and 39 students ranged from 2 to 12 persons (full-time equivalents). However, there is some correlation between enrollment and cost, as shown by the average costs for departments in various enrollment brackets (see table 40). In general, those departments with larger enrollments operate with higher student-staff ratios and with lower staff costs per student. That the differences in these averages are not greater is due to the fact that departments with small graduate enrollments tend to provide relatively less *separate* graduate instruction than departments with larger enrollments. Incidentally, the

TABLE 40.—RELATION OF STUDENT ENROLLMENT TO STUDENT-STAFF RATIOS AND COSTS PER STUDENT[a]

Number of students 1951–52	Number of departments	Average ratio of students to staff (full-time equivalent)	Staff cost per student: instruction only	Staff cost per student: instruction and research

80 and over	4	8.0	563	905
Total	37			
Average for the combined group		7.1	595	952

[a] For source, see table 39.

fact that the institutions with very large enrollments had a lower student-staff ratio and higher average cost per student than some of the middle-sized departments does not lead to the conclusion that graduate departments necessarily have a u-shaped cost curve. The relatively high cost for the large departments is explained by the fact that these are distinguished departments with high salaries, heavy expenditures for research, and large and varied staffs. As shown in table 40, the average staff cost per student for the 37 reporting institutions was $952.

I do not wish to draw any firm conclusions from these data. Yet I think they do suggest an unevenness in the cost and quality of graduate work in economics offered in various institutions. They also indicate that graduate instruction is expensive, especially when conducted on a

small scale. This, it seems to me, should give pause to those institutions which are contemplating entering the field, and also should raise questions at other institutions regarding the desirability of leaving the field. But these are big issues in which many factors besides cost and efficiency are often decisive.

Administrative Organization

The discussion thus far has referred to the department of economics as though there were only one such department in each university. This is, of course, far from the actual situation at many institutions. It is perhaps more common for graduate training and research in economics and closely related fields to occur within each of several administrative units. Among these are: (1) the department of economics, (2) the school of business, (3) the department of agricultural economics usually located in the college of agriculture, (4) the department or school of home economics, (5) the college of law, (6) the institute of labor relations, (7) various area study groups such as the Russian institute or the institute for Latin American studies, (8) the institute of international relations, (9) the department of industrial management in the college of engineering, (10) the division of industrial psychology in the department of psychology, and (11) other miscellaneous institutes, committees, commissions, task forces, etc., such as the institute of communications research, institute of public administration, division of social science research, or council on housing research. The purpose of this section is to consider the causes and consequences of this administrative fragmentation of economics.

Historically, the process of fragmentation began 50 or more years ago with the widespread organization of schools of business. In recent years, however, the process has apparently speeded up as literally hundreds of special agencies having connections with economics have been created. The resulting organization of the field is complex—some think chaotic. Economics, however, is not the only field in which this kind of fragmentation has occurred. Indeed, it is a widespread phenomenon, a marked characteristic of academic development in our time.

The administrative fragmentation of the field of economics may be explained in terms of several objectives or forces. First, it has occurred as a result of the effort of universities to mobilize their resources to deal effectively with a wide variety of social issues, particularly those having inter-disciplinary aspects. Many of the schools and institutes have grown out of the attempt to achieve a workable administrative structure for fruitful interdisciplinary relationships. The labor relations

institutes have been notable examples of this; even the business schools have important interdisciplinary aspects.

Second, the fragmentation has occurred as a result of efforts to meet the demands for various kinds of specialized training in agricultural economics, business, labor relations, international relations, housing, public administration, etc. While these instructional programs might have been carried on in conventional departments, it was thought that more practical or more realistic or more concentrated training might be given in a special administrative division.

Third, the fragmentation has occurred as a way of seeking favorable public relations through creating special autonomous units which would establish and maintain contacts with special interest groups such as labor, agriculture, or business. An incidental purpose has been to emphasize work in areas having news value and popular appeal because of a direct relation to important issues of the day.

Fourth, the creation of these special units has occurred as a device for raising money. Apparently, it has been easier to obtain funds for a special unit having an intriguing title and an assignment closely related to current issues than to finance the same work in the traditional departments. The foundations have almost certainly contributed to the fragmentation. A special situation has been the creation of separate departments of agricultural economics because of the availability of Federal funds for research and extension. The recent availability of Federal funds for contract research has also stimulated the further development of separate administrative units.

Fifth, these special units have been created to give scope to the ambitions of energetic academic promoters or to reduce friction between staff members with varying interests and points of view—especially to separate those with theoretical interests from those with more "practical" or "programmatic" interests. This last has been a particularly important force in causing the separation of business schools from economics departments. Those economists whose interests have been relatively theoretical have often not been congenial colleagues for those of a more practical turn of mind. The former are sometimes considered visionary, impractical, and radical by the latter; and the latter are sometimes considered crass and mundane by the former. These attitudes are evident in many institutions. I regret to say that in some, the economic theorists are accused of intellectual snobbery, and as a result there are strong anti-theoretical attitudes on the part of persons in the applied fields. In some institutions, the pressure to organize separate divisions has resulted from an effort to relieve students of the requirements (especially economic theory) of the economics department. This is one of the motives underlying the movement to offer a separate Ph.D.

in business administration and in agricultural economics. I have even heard the suggestion from a group of accountants that no student should be permitted to sit for the C.P.A. examinations unless he has been trained in a "school" of accountancy having a dean who reports directly to the president of the university.

What are the consequences of this fragmentation from the point of view of graduate education in economics? In my judgment, many of the consequences are undesirable. Perhaps important ends have been attained through this administrative cutting up of economics but I doubt if one of them has been improvement in the education of economists or in the progress of the discipline. There are several principal consequences. First, the development of economics has been uneven—some fields such as agricultural economics, business, or labor, upon which large funds have been lavished, have been elaborated in great detail by an army of specialists, whereas other fields like consumer economics or economic history have been given relatively little support.

Second, various types of economists, located in separate administrative units, have not been able to maintain as close communication with one another as would have been desirable. For example, the economics of the firm, as developed by economists, has been relatively out of touch with developments in the business or engineering schools; or the theory of wages has not always been informed by the knowledge of specialists in labor relations. Conversely, the students in business or labor relations have often lacked the benefit of developments in theory. It can be argued, of course, that administrative barriers can be surmounted by those who genuinely wish to keep up with developments throughout the field; I am convinced, however, that communication tends to be much closer when these barriers do not exist.

Third, the training of economists tends to be more highly specialized and narrower when it occurs in separate administrative units than when it occurs in a more comprehensive unit. Students in business, agricultural economics, labor relations, etc., are likely to acquire less than optimal breadth—even for successful professional work in these fields. Similarly, students of general economics will often receive a narrower training in a department stripped of the applied fields than in a more inclusive department.

Fourth, the specialized units tend to acquire close contacts with—and sometimes to be controlled by—the outside groups (especially business, agriculture, and labor) whose activities they are studying. This fosters ideological biases and leads to difficulties in maintaining academic freedom and scientific objectivity. Even the general economics department, when it has been divorced from the more practical aspects of

the field, probably tends to develop its own ideological biases. At least, those in schools of business often charge economists with biases toward government planning, deficit spending, etc. Staff members of some business schools have reported to me that they advise their students not to take work in the "radical" economics departments.

Fifth, the specialized units tend to command a large share of the funds available for economic research and thus starve the general economics department. There may also be a tendency among the institutes to engage in those kinds of research or other activities for which money can be raised without careful regard to the development of the entire field or to the progress of basic areas.

Sixth, as a result of the setting up of many administrative units, the urgent problems close to great public issues of the day are handled in the specialized units, leaving only the more general and theoretical areas—which are less related to practical issues—for the department of economics. This means that the department tends to lose touch with the real world. At the same time the specialized units lose contact with the discipline and the contributions of theory, and tend to become "unintellectual"—to quote one business school dean.

Seventh, the fragmentation of the field, by dividing the student body into several separate groups, sometimes prevents any of the administrative units from achieving the enrollments needed for efficient operation.

This is a strong indictment of the fragmentation which has become so widespread. Some of my critics think it an exaggerated indictment, as it may well be. It may be readily conceded that the problem does not exist in every university. In some institutions the fragmentation has been only skin deep—it has affected form, not substance. In some cases useful results have been achieved through the creation of new administrative units. In some institutions, the several administrative subdivisions have worked out well-balanced programs and harmonious relationships. Nevertheless, I maintain that there is a serious problem.

What is to be done about the administrative organization of economics? Perhaps nothing *can* be done. We may be at the mercy of great social and intellectual forces which are bringing about a revolution in the classification and relationship of various fields and sub-fields. Perhaps it is too much to expect that in a field as dynamic as economics we shall ever be able to crystallize an organizational pattern. Yet I believe there are certain principles which ought to govern in this matter. The basic problem is one of the relationship among substantive areas which at one time were considered to fall wholly or partly within economics. But the problem appears also in the relationship between the economics and other areas which have traditionally been assigned to other

fields, e.g., sociology, political science, law, psychology, philosophy, etc.

First, the integrity of the traditional field of economics should be protected so far as practicable, and no parts of economics should be removed to other administrative units unless the reasons for doing so are overwhelming. The burden of proof for so doing should be on those who propose the change, and adventitious circumstances or temporary expediency should seldom govern.

Second, in many cases, it will be possible to accomplish objectives by establishing *ad hoc* curricula or *ad hoc* research teams within departments of economics or through interdepartmental cooperation—rather than by organizing new administrative units. The problems have often been satisfactorily solved in this way. When, for purposes of public relations or money-raising, it seems desirable to create new administrative units, they should whenever possible be placed *within* rather than outside departments of economics.

Third, all economists in a university should be in communication with one another. This is facilitated by having their offices in close proximity, by their having a formal connection with the economics department, and by providing seminars and discussion groups at which they can learn about each other's work. In this connection communication is a two-way process. It is frequently reported that theoretical economists are more interested in outward rather than inward communication. Many staff members of business schools, labor relations institutes, and departments of agricultural economics complain that they have not been able to establish a two-way communication with the economists of the economics department.

Fourth, at least the common core fields of economic theory, economic history, and history of economic thought should be retained in the economics department which should do the teaching of these subjects for all students regardless of their administrative affiliation.

Fifth, general economics departments should develop special courses for students whose major interest lies in fields related to economics but who are not to become primarily economists, for example, students of accounting, of industrial management, of industrial psychology, etc. To expect these students to meet the same requirements as majors in economics is unreasonable. It can lead only to friction and to efforts to by-pass the department. Many cases have been reported to me of students, in various fields marginal to economics, who have been prevented from getting their Ph.D.'s because of unwillingness or inability to meet theory requirements designed for economics majors. Some departments have tried to meet this situation by holding the requirement but altering the courses, thus diluting the training of their own economics majors. This, I feel, has been unwise.

Finally, sixth, I believe that many of the organizational difficulties could be prevented or overcome if all of the social sciences and their related applied fields could be brought together into one large administrative unit having a flexible departmental structure. Such an administrative unit, if under capable leadership, would facilitate communication among the staff-members within each discipline and also communication among staff-members of related disciplines. It would simplify the administrative problems involved in developing interdisciplinary programs. It would help to maintain closer and mutually helpful connections between basic and applied fields. It would help to break down the rigid administrative and intellectual lines that separate various disciplines.

But even when all of these things have been done, many of the organizational problems will remain. These are problems we must live with in an intellectual world which does not lend itself to neat compartmentalization.[8]

Evaluation of Departments

In any discussion of educational institutions, their staffs and their facilities, the question inevitably arises as to what devices might be employed to stimulate existing departments to improve, or to prevent unqualified departments from continuing in (or entering) the field. One answer to this is, of course, demand and supply. This is not a complete answer, because the incentives to the supply of graduate work are not always confined to the meeting of a demand. Moreover, the consumer is not always able to choose intelligently, and often is influenced by subsidies, by personal relationships, or by the convenience of remaining near home.

A second answer is the pressure of opinion within the profession. It is sometimes held that inferior graduate work will be found out, and that those responsible will lose caste within the profession; conversely, that superior graduate work will be recognized and will bring professional status and honor to those responsible. It is true that public opinion does exert considerable pressure in this respect. Unfortunately, however, communication within the profession is far from perfect, and there are some departments of economics which have so lost contact with the outside profession that they do not feel the pressure of professional opinion.

[8] For a discussion of the subject of fragmentation with reference to political science, see American Political Science Association, Report of the Committee for the Advancement of Teaching, *Goals for Political Science*, New York, 1951, pp. 86-97. On administrative relationships between departments of economics and schools of business, see Horace Taylor (editor), "The Teaching of Undergraduate Economics," *American Economic Review* (supplement), Dec. 1950, pp. 121-24.

A third answer is accreditation by an outside agency. Several professional associations have entered this field, e.g., the American Chemical Society and the American Association of Collegiate Schools of Business. Apparently accreditation has sometimes achieved significant results, its greatest benefit deriving from the fact that it requires the careful study of standards and represents an important educational experience for all concerned.[9] As anyone connected with higher education knows, however, accreditation is also subject to abuses—especially because the standards tend to be weighted with those criteria which are objective (number of staff, degrees, dollars spent, administrative organization, etc.) rather than with those qualitative considerations which are all-important in education. Sometimes, accreditation has monopolistic overtones, and it tends to impose uniformity and to discourage experimentation. Formal accreditation by an outside agency is far from a panacea, and I am not prepared to recommend that the American Economic Association at this time enter the business of accreditation.

I believe, however, that graduate departments should from time to time subject themselves and their programs to examination by qualified outside members of the profession. I believe that every graduate department should arrange for such an examination by an outside visiting committee at least every five years. The report of the examinating committee should be confidential for use by the department and the general administration of the university. The examining committee should be appointed not by the department to be examined but by the president or graduate dean of its university, or by an outside agency such as the American Economic Association. The Association should stand ready to cooperate both in formulating standards for judging departments and in nominating *ad hoc* committees for investigating departments. The expense of this work should be borne by the university whose department is under review.

To carry out this recommendation, the Association should establish a standing committee the function of which would be to formulate standards for graduate education, to encourage universities to place their departments under review, and to nominate *ad hoc* committees for the investigation of particular departments.

[9] For a discussion favorable to accreditation, see Association of American Universities, "Report of the Special Committee on Accrediting Graduate Study," *Journal of Proceedings and Addresses,* 1945, pp. 39-70.

Chapter 13

INSTRUCTIONAL METHODS

This chapter is in no sense a comprehensive treatment of instructional methods. It presents several issues and offers a few suggestions regarding procedures in the teaching of students of economics at the graduate level.

Independent Study

A major issue in graduate study concerns the degree of independence with which the student pursues his work. At the one extreme, his entire graduate program would consist entirely of a series of formal courses (American undergraduate style) with systematic coverage of fields, specific assignments, and frequent examinations. At the other extreme, the student would be entirely on his own, his only requirement being that of satisfying an examining committee at the conclusion of his studies (European style). In the latter case, he would be free to attend lectures and seminars and to benefit from the guidance of faculty members, but his work would be entirely independent and he would be judged only by his final performance and not by his day to day work.[1] In practice, American graduate education falls between these extremes, but there are substantial differences among institutions with respect to the degree of independence of students. In most, despite protestations to the contrary, graduate education is closer to the American undergraduate pattern than to the European pattern. Considerable emphasis is placed upon systematic courses, course examinations, hours of credit, residence, and the other aspects of American college routine. The deviations from the undergraduate pattern include the seminars in which special topics or problems are treated, a limited amount of independent study or research, and the writing of theses and dissertations. The various comprehensive examinations are supplementary to the examinations given in courses and seminars.[2] Moreover, the comprehensive examinations are often

[1] Several valuable papers on the teaching of economics in various countries were presented at a meeting sponsored by the International Economic Association at Palloires (Haute Savoie), France in August 1951. These papers were published in mimeographed form.

[2] On the whole, I favor the use of course examinations and grades, as well as a comprehensive examination, in judging students. The former provide independent judgments of the student in a variety of situations and by a variety of professors acting independently. The latter provides only a single collective judgment. However, I believe that the comprehensive examinations should cover *fields* and not courses.

merely additional examinations over particular courses rather than examinations covering entire "fields"—as they purport to be. The questions which this situation suggest are: Would graduate education be improved if it represented a sharper breaking away from undergraduate procedures? Would it be desirable to place less emphasis on formal systematic courses and to give greater scope to seminars, independent study, and research?

Unfortunately, I do not know the answer to this question. Most departments are led toward undergraduate methods by the fact that many students bring to graduate study an inadequate intellectual background. It seems necessary to drill them systematically on fundamentals before letting them spread their wings. Yet I have the uneasy feeling that our procedures delay rather than advance intellectual independence and maturity. Particularly, I feel that something might be done for the more gifted students to relieve them of going through the routine of earning "credits" and meeting various formal requirements.

A promising proposal in this direction, with which Professor Friedman of the University of Chicago is experimenting, would be a "workshop" for selected second-year graduate students. They would devote their entire time to this enterprise. Only those students would be eligible who had adequate preparation in theory, statistics, and money prior to entering graduate school, and who had completed rigorous graduate work in the "core" fields during the first graduate year. Then, during the second year, they would devote full time each semester or quarter to one problem in a selected field. They would work on this problem in close consultation with the indicated professor, and develop a report in publishable form (or as nearly so as possible). Then, in the third year, the student would proceed to his dissertation. The workshop proposal has the advantage of giving students the opportunity for independent and concentrated work.

Another possible method of achieving more independence would be greater use of seminars. Unfortunately, it seems that seminars have a way of degenerating into straight courses—so a sharp break with customary practice may be necessary to achieve the desired result. Still another device is to permit superior students to engage in independent study for "credit" under the guidance of one or more professors.

Creative Activity

A closely related problem concerns the balance between (a) active and creative work of students (solving problems, original writing, discussing issues) and (b) passive and absorptive pursuits (reading and listening to lectures). A possible criticism of much graduate work is

that it consists too largely of the latter. While no one would argue that reading and listening are unnecessary, there is a real question as to whether the reading and listening that is done for its own sake and without problems to solve or questions to answer is as useful or meaningful as that which is directed toward specific problems and questions. An increase in the amount of creative work done by students would doubtless improve graduate education. This, incidentally, provides a strong argument for the retention of the master's thesis or its equivalent. Some attention also might be given to planning the topics and schedules of the papers and problems a student will do for his various courses. This would make it possible to space deadlines conveniently, and to provide for the inclusion of various kinds of topics, e.g., empirical, theoretical, public policy, etc.

Another type of creative activity is discussion not only in the classroom but outside. Apparently a serious lack in many departments, as reported by both students and faculty, is the dearth of facilities and the absence of traditions conducive to vigorous discussion. Common rooms, student offices, graduate dormitories, student clubs, and gatherings of students at faculty homes are all helpful in this regard. Universities located in small towns have an advantage in that a campus student life is possible. A requirement for student discussion is an intellectual spirit which apparently requires leadership and the interaction of vigorous personalities. Without this, even the most favorable physical surroundings will not create an atmosphere of fruitful discussion.[3]

A topic closely related to independent and creative student work is the use of the problem or case method in instruction. So far as I know no one proposes that graduate education in economics be conducted entirely by the case method. There are many who recognize the merits of this method for certain purposes and several experiments along this line are under way. The experience of the Harvard Graduate School of Business is well known. Also the several graduate schools of public administration have developed and used case materials with apparent success. In dealing with problems of public policy, the use of cases would undoubtedly be helpful in the teaching of economics at the graduate level—especially as a way of dealing with public policy issues. The use of cases is of great utility in bringing economic principles into touch with reality, in illustrating the complexity of the real world, in showing the strength and limitations of economics, in demonstrating its relations to other areas, and in stimu-

[3] On the general subject of independent study, creative activity, etc., see Horace Taylor (editor), "The Teaching of Undergraduate Economics," *American Economic Review* (supplement), Dec. 1950, pp. 150-1, 154-5.

lating interest in the field. Those who have experimented with the case method in economics advise the use of a few selected cases intensively analyzed rather than many superficially studied. However, it must be recognized that the difference between a "case" and an "illustration" is only one of degree; many teachers have been using the case method without so describing it or considering that they were departing from conventional teaching methods. Indeed much of economic history is, or could be, the study of cases. Yet something new and useful has been added when particular episodes in public policy formation are investigated carefully with the object in mind of "solving" the problem.

The great difficulty in using the case method of instruction is to find suitable materials for the presentation of cases to students. To meet this problem, the law colleges, the Harvard School of Business, and the Schools of Public Administration have been forced to devote enormous energies to the development of case materials. To do the same for economics would require a similar major effort. Could the American Economic Association provide leadership in the development of case materials? I am inclined to think so. I suggest, therefore, that a committee on the case method of instruction be appointed to consider needs, to inventory present resources, and to plan methods of augmenting these resources. The experience of the public administration group under the leadership of Dr. Harold Stein would be extremely useful in this respect.[4]

Incentives and Rewards for Distinguished Scholarship

Graduate students probably do not need, and might resent, attempts to apply the elaborate system of awards, prizes, honorary memberships, etc., which are used to spur undergraduate students on to greater accomplishment. However, something useful might be done to honor or reward those graduate students who have done distinguished work. The David A. Wells Prize at Harvard is an example of a well-known award of this type. It would be possible for many graduate departments of economics to do more than they now do to provide special incentives for exceptional work. Possible devices would be to publish outstanding theses and dissertations, to award prizes for outstanding scholarship, or to provide special honorary fellowships. The American Economic Association might enter this field by offering prizes for the best theses or dissertations, or by publishing them completely or in abstract form.

Standardized Examinations

At present, most departments provide comprehensive examinations

[4] See Harold Stein (editor), *Public Administration and Policy Development: A Case Book*, New York, 1952.

in written and/or oral form. The written examinations rely largely on broad general questions requiring fairly lengthy discussion, and the oral examinations are usually informal and relatively unplanned. There is reason to suppose that these examination procedures are not always as rigorous or as objective as might be wished. The difficulty of achieving good examination procedures is especially difficult in the departments having small numbers of students. This is true for two reasons: (1) the close personal relations of students and professors makes objective judgment difficult and it makes the failing of a student, when necessary, a most painful experience; and (2) it is difficult to develop comparative standards when the number of students is very small. Even in larger departments, the question arises as to how their standards and the quality of their students compare with those in other universities.

There are two possible solutions to this problem. One would be to employ outside examiners. Many professors favor this plan. It is common in Europe, and is used by several liberal arts colleges in the United States. It presents, however, serious administrative and financial difficulties, especially when the number of students to be examined is small.[5] A second possible solution would be the use of standardized examinations which would be given to students in many universities. Such examinations could be provided, for each of the principal fields, at the master's and the Ph.D. level. The papers from all universities would be judged by one committee, and the grades or scores reported on a confidential basis to each of the participating departments. The examination might be of the "essay" type or it might combine essay and objective questions.

While no department would wish to rely entirely upon an outside standardized examination in judging its candidates, such a procedure would help both in judging the ability of students and in measuring the effectiveness of the department in selecting and educating students. The disadvantages of the outside examination are that it might lead to standardization, and that it might tend to divert the educational process from those areas which the professors consider important to those subjects which are likely to be covered on the examination. The influence of these factors is seen clearly, for example, in the education of accountants which is often geared to the objective of passing the C.P.A. examination. Outside examinations for economists, I think, ought never occupy a position analogous to that of the C.P.A. examinations. They should be thought of as advisory and as supplementary to existing examination procedures. If conducted in this way, they

[5] About half of the professors queried on this proposal were favorable and half opposed.

might exert a helpful influence toward clarifying objectives and toward raising the quality of graduate education in economics.

If such standardized examinations were to be given, who should administer them? This task might be carried on under the aegis of the American Economic Association possibly with the cooperation of a professional agency such as the Educational Testing Service. I recommend that the Association explore the possibility of developing a program for conducting nation-wide examinations for graduate students in economics.

Miscellaneous Suggestions

In my visit to graduate departments of economics, I observed or heard about several educational devices which seem to work well and which might be employed more widely. These included the following:

(1) Mimeographing and distributing seminar papers in advance of their presentation.
(2) Publication of seminar papers, together with student critiques, after the papers have been presented, discussed, and revised.
(3) Organization of small groups of students for review prior to comprehensive examinations.
(4) Examination of students on a list of important books as part of the comprehensive examinations.
(5) Publication of examination questions for prior years.
(6) Reading of written comprehensive examinations, for each field, by several professors each of whom does not know the judgment of any of the others.
(7) Reading of written comprehensive examinations without the student names appearing on the papers.
(8) A paid graduate student assistant to handle student relations, including social functions, use of common rooms, discussion groups, etc.
(9) Credit given for proficiency examinations in lieu of certain courses—especially for superior students.

Chapter 14

GRADUATE STUDY IN ECONOMICS: A NATIONAL VIEW

The precise number of universities in the United States and Canada which offer graduate work in economics is difficult to ascertain because the number fluctuates from year to year, and it is difficult to classify some institutions which theoretically *offer* graduate work but seldom or never actually award any advanced degrees. During the two years 1949-50 and 1950-51, 126 U. S. institutions actually awarded one or more master's degrees in economics.[1] And during the post-war years 1945-6 through 1950-1, 67 institutions in the United States and Canada actually awarded one or more Ph.D.'s (see table 41). On the basis of these figures, one would guess that there are about 135 institutions in the United States and Canada which offer and sometimes give graduate work in economics. Of these, perhaps 70 award *both* the master's degree and the Ph.D., and 65 give only the master's degree.

Enrollment and Number of Degrees

In 1951-52 these institutions had a combined graduate enrollment in economics of roughly 3,000 students.[2] During recent years they have awarded about 800 master's degrees in economics per year[3] and from 200 to 400 Ph.D.'s.[4]

No data are available on the trend in the number of master's degrees awarded, but figures are available on the number of Ph.D.'s awarded over the period 1925-26 through 1950-51. These data are presented in table 43, and comparisons are made with the number of doctorates awarded in all fields. These figures show a generally rising trend in

[1] The number awarding master's degrees in 1950-51 was 102 (see table 42) and in 1949-50, 113. Some institutions awarded master's degrees in only one of these years, hence the figure 126 exceeds either of these numbers. See U. S. Office of Education, *Earned Degrees Conferred by Higher Educational Institutions,* 1949-50. Data for 1950-51 were kindly made available to me by Mr. Robert C. Storey of the Office of Education.

[2] This estimate is based on enrollment figures supplied by 37 institutions. The total was estimated by adjusting the reported figures on the basis of ratio of advanced degrees awarded by all institutions to the number awarded by the reporting institutions.

[3] According to the U. S. Office of Education the following numbers of master's degrees in economics were awarded (cf., table 42).

1946-47	693
1948-49	863
1949-50	921

Concentration of Graduate Enrollments

As shown in tables 44 and 45 the universities offering graduate work give widely varying numbers of degrees. More than a third awarded fewer than one doctorate per year on the average, since the war, and only six awarded 10 or more doctorates per year. About a third of the universities awarded one or two master's degrees (in 1950-51) and

only 10 awarded more than 20. This suggests that a large part of the graduate work of the country is concentrated in a few institutions. Table 46 lists the 10 leading universities in number of Ph.D's and master's degrees awarded and indicates the percentage of degrees granted by each. As shown in the table about 60 percent of all doctorates and 43 percent of all master's degrees are awarded by 10 insti-

tutions.[5] The remaining 40 percent of the doctorates are divided among 57 other institutions and the remaining 57 percent of the master's degrees are divided among more than 100 other institutions.

These data on the distribution of graduate degrees among institutions raise the question of whether graduate study is quantitatively too concentrated within a few institutions—or whether it is too widely dispersed among many institutions, or both. I have already considered economies of scale with reference to graduate education (Chapter 13). My tentative conclusion was that it is probably too dispersed—that better and more efficient education would be possible if the student population could be drawn together into a somewhat smaller number of institutions.

TABLE 46.—LEADING INSTITUTIONS IN NUMBER OF ADVANCED DEGREES AWARDED IN ECONOMICS

Ph.D.			Master's degree		
Rank	Institution	Percentage of Ph.D.'s awarded 1945–46 through 1950–51[a]	Rank	Institution	Percentage of all master's degrees awarded 1949–50 and 1950–51[b]

[b] Basic data from U. S. Office of Education.
[c] Among the first ten for both Ph.D.'s and master's degrees.

I queried graduate professors on this point. With reference to doctoral students, the most frequent answer was that the distribution of students is too highly concentrated *and* that too many institutions are offering graduate work. With reference to the master's degree, there was less concern over the distribution of students.

[5] Six institutions are among the leading ten for both the Ph.D. and the Master's degree (Columbia, Chicago, Wisconsin, Illinois, Minnesota, and New York). Apparently the concentration has not been so great for the post-war period as it was in pre-war years. Whereas the top 10 institutions in the period 1945-46 to 1950-51 produced 60 percent of the doctorates, the ten leaders in 1938-39 to 1941-42 produced 66 percent of the doctorates.

In conversations on this subject, it was sometimes pointed out that excessive concentration of graduate students within a few universities might on the whole be disadvantageous in that it would reduce the amount of diversity in types of programs offered and in points of view represented. Hence it was thought desirable to maintain considerable freedom of entry into the field of graduate education in economics, and not to move toward some sort of accreditation precedure which might limit the number of institutions too rigidly. Moreover, it was pointed out that size alone is no guarantee of quality, and that in fact some of our most distinguished graduate departments are very small—some by deliberate choice. Nevertheless, my general judgment is that too many institutions are offering graduate work and competing for the relatively small flow of students. Ample diversity could still be maintained if the number of institutions were substantially diminished. In point of fact, very little diversity is obtained merely through large numbers because most of the smaller institutions are very conservative and follow consistently the patterns of the larger ones. Today, most of the experimentation and flexibility is to be found in the large and well-known institutions.

My principal conclusion would be a word of caution to institutions which are considering entry into the graduate field, a suggestion to those already in the field marginally to consider whether withdrawal might not be wise. The conclusion stems in part from considerations of costs as presented in Chapter 12.

[c] Schedule X: 218 respondents.

At the other extreme, there are a few institutions (probably not more than 2 or 3) at which the number of students possibly exceeds the optimum. Such institutions might well consider limiting their enrollments. It is possible that general enrollment trends and the tapering off of G.I. benefits will accomplish the result without specific action.

The Flow of Students

As shown in table 47, graduate students in economics apparently took their bachelor's degrees in many types of institutions, though the great majority did their undergraduate work in larger "universities" rather than smaller "colleges."[6] As they proceeded to graduate study, a substantial number stayed at the same institution for the master's degree and some stayed on for the doctorate, but a majority moved to another institution at some point in their graduate careers. Table 48 shows the institutional history of three groups of graduate students, and indicates the considerable tendency toward moving from one institution

[6] Cf. L. A. Froman, "Graduate Students in Economics," *American Economic Review*, Sept. 1952, p. 607.

to another. Table 49 presents data on the geographic movement of graduate students during their graduate careers. This table indicates that a third to a half of the students took their graduate work in the same geographic region as their homes but that a majority took their graduate work elsewhere.

When students were asked how they happened to select their graduate institutions, a large minority mentioned such practical matters as geographic proximity to home, finances, and evening school. Another

TABLE 49.—MIGRATION OF GRADUATE STUDENTS IN ECONOMICS: COMPARISON OF GEOGRAPHIC REGIONS OF HOME TOWN, UNDERGRADUATE COLLEGE, AND INSTITUTION GRANTING HIGHEST DEGREE[a]

	Graduate students in residence 1951–52[b]	Former graduate students who received advanced degrees in 1939–40 or 1949–50[c]

[a] Geographic region refers to the standard regions used by the U. S. Census. Home town was defined as "home town at the time you finished secondary school."

[b] Schedule IX: 140 respondents.

[c] Schedule X: 218 respondents.

large group mentioned the high standing of the institution or department. Surprisingly few mentioned desire to study with particular professors or type of work offered.

In general, professors believe that diversity of graduate student population with reference to geographic origin and institution of bachelor's degree is desirable. They also believe that it is good for students to have experience at more than one institution during their academic careers. A substantial number would prefer wider diversity as to geographic and institutional origins of their own student bodies. When questioned on what could be done to increase diversity, many mentioned greater financial aid with which to attract students and nearly as many mentioned departmental improvement.

Specialization and Cooperation

As I traveled about the country visiting graduate departments of economics, I was impressed with the lack of specialization and cooperation among institutions. The great majority of institutions are offering a fairly standardized program with broad coverage of many fields. Little effort is made by institutions to differentiate their offerings or to take advantage of their special resources. This is all to the good to the extent that basic training in fundamentals is essential in the education of all economists. Yet one might have thought that particular institutions would attempt to develop distinction in special fields, for example, government and business, international economics, or labor relations. But one finds remarkably little of this specialization.

Similarly, one finds impressively little cooperation among institutions—even among those located near each other. For example, there is apparently little tendency to encourage one's students to take specialized work at other institutions—even when the quality of such work may be superior. There is little exchange of faculty or participation in the seminars of other universities.

There are notable exceptions to these generalizations, one of the most interesting being the cooperative graduate program offered by the group of colleges in Claremont, California. Yet the lack of specialization and cooperation is almost everywhere more impressive than its presence.

I do not have any clear recommendation as to what might be done about duplication, lack of specialization, and lack of cooperation. The Hotelling principle that competitors tend to converge toward the "middle" of the market may be at work here. At least it seems that each institution might examine its own resources and potentialities carefully, and attempt to direct its activities toward those areas in which it can make the greatest contribution to the nation's facilities for training economists. It is not necessary that every institution try to do everything.

Facilities in Washington and New York

The suggestion has been made frequently that a liaison agency is needed in Washington to represent and serve the graduate departments of economics throughout the country. This agency might perform a variety of functions. The following are some of those which have been suggested.

First, the agency might maintain contact with the many students who are employed in Washington prior to completing their graduate work, and encourage and assist them in completing their graduate studies. Washington has become notable for the number of economists em-

ployed there who have completed all their graduate work "except the dissertation." Presumably, then, the functions of the agency might range from "encouragement" or assistance to actual supervision of the writing of dissertations. In the latter case, it would serve as representative of the universities of original jurisdiction—the latter actually awarding the degrees.

Second, the agency might offer seminars or courses which could be taken by students with or without credit in their home universities.

Third, it might assist candidates by opening up sources of data or research information in Washington, or by offering advice or assistance in the carrying out of research projects.

Fourth, the agency might provide research associateships for young economists—either for graduate students or University staff members.

Fifth, the agency might assist in organizing and administering a program for in-service training of graduate students who are employed in the Federal government.

Sixth, it might provide an ongoing research program which students could observe.

If all of these things were done, the agency would indeed be a busy place. But any one or more of these things would be useful, and the more the better. The main purpose of the agency, from the point of view of academic departments of economics, would be to provide opportunities for students to gain experience in Washington and to encourage and assist those students who are employed in Washington to complete their graduate studies.

The question is: what agency might perform these functions? Many have suggested the Brookings Institution. From the point of view of its history, location, and facilities it would be ideal. I have discussed the matter with Dr. Robert D. Calkins, the new President of the Brookings Institution who tells me that he is interested in exploring the possible usefulness of this organization in the training of economists (though he is in no sense committed to any of the proposed functions listed above). I believe that the profession, perhaps represented by the American Economic Association, should attempt to promote the development of such facilities in Washington.

It is also conceivable that similar facilities could be provided in New York, for example, by the National Bureau of Economic Research. That institution already maintains close relationships with many universities and already offers research associateships and fellowships to young economists.

"Adult" Education for Economists

Finally, I shall consider the question of whether the economic profession offers adequate facilities for its members to "keep up" with

current developments in the field. The principal facilities now employed are professional journals, professional meetings, and contact with colleagues. The latter is not available to many economists who are in smaller colleges or in positions in business and government where the number of professional colleagues is small. Professional meetings, as now conducted, are criticized by many as not helpful for educational purposes—though most consider them useful on other grounds. And there is a surprising amount of complaint directed toward the journals, which are charged with being too esoteric and theoretical.

I do not wish to be associated with these criticisms; yet I feel that more and better facilities could be provided. The following are some suggestions:

1. That sabbatical leaves should be available for all economists including those in small colleges, in government, and in business. It would be extremely helpful if economists in government and business could have extended periods of time off to reflect and to reacquaint themselves with contemporary thought in economics.
2. That a few leading universities might provide short courses or extended conferences intended primarily for the teaching of economics in smaller colleges.
3. That the American Economic Association might supplement the annual meeting by sponsoring smaller and more extended conferences on specialized subjects. A model of such conferences would be those sponsored by the International Economic Association, by the National Bureau of Economic Research, or by the Social Science Research Council.

Appendix

DESCRIPTION OF QUESTIONNAIRES

Twelve separate questionnaires were utilized in the study. In the text of the report frequent references are made to those questionnaires by schedule numbers. The purpose of this appendix is to provide a brief description of each of these schedules.

Schedule I was sent to chairmen of departments of economics in institutions where there was some doubt as to whether graduate work is offered. Its purpose was to ascertain whether graduate work is offered and the number of degrees awarded during 1945-46 to 1950-51. Number mailed, 108; number returned, 61.

Schedule II was sent to the chairmen of all departments of economics offering both the master's degree and the Ph.D., and also of all other departments which granted 4 or more master's degrees (but no doctorates) in economics during the two years 1949-50 and 1950-51. Its purpose was to obtain data on practices and policies in the selection and training of first-year graduate students in economics. The specific topics covered were:

admission
elimination of unfit students
residence requirements
credit and grade requirements
foreign language requirements
courses of study
minor fields
thesis
examinations
flexibility
superior students
advisory system
placement
plans for revision of program
research

Number mailed, 94; number returned, 68.

Schedule III was sent to the same department chairmen as Schedule II. Its purpose was to obtain statistical data on staff, enrollments of first-year graduate students, financial assistance to students, and mailing lists of present and former first-year students. Number mailed, 94; number returned, 59.

Schedule IV was sent to staff members (other than department chairmen) who are engaged at least part-time in graduate instruction in economics in the institutions to which Schedules II and III were sent. Its purpose was to obtain opinions and judgments regarding present practices in the selection and training of first-year graduate students in economics. Specific topics covered were the same as those listed above for Schedule II. Number mailed, 99; number returned, 61.

Schedule V was sent to chairmen of all departments of economics which granted 3 or more Ph.D.'s in economics during the years 1945-46 to 1950-51. Its purpose was to obtain information on the practices and policies in the selection and training of candidates for the Ph.D. in economics. Its general purpose and coverage was similar to that of Schedule II. Number mailed, 53; number returned, 27.

Schedule VI was sent to the same department chairmen as Schedule V. Its purpose was to obtain statistical data, relative to the training of Ph.D. candidates, similar to that obtained in Schedule III on master's candidates. Number mailed, 53; number returned, 32.

Schedule VII was sent to staff members (other than department chairmen) who are engaged at least part-time in graduate instruction in economics in the institutions to which Schedules V and VI are sent. Its purpose was to obtain opinions and judgments regarding present practices in the selection and training of candidates for the Ph.D. Specific topics covered were the same as those listed above for Schedule II. Number mailed, 79; number returned, 59.

Schedule VIII was addressed to persons serving as economists in a wide variety of large business firms. The list to which it was sent was constructed with the advice of several active business economists: Walter E. Hoadley, Jr., Wesley Lindow, Roy L. Reierson, and John Wills. The purpose of the questionnaire was to obtain information about the work of business economists, and to get their opinions and judgments regarding the training of economists for positions in private business. Number mailed, 103; number returned, 49.

Schedule IX was sent to graduate students in residence during 1951-52. Names and addresses of these graduate students were provided by department chairmen who responded to Schedules III and VI. A questionnaire was sent to every third graduate student so listed. The purpose of the questionnaire was to provide personal data (age, geographic origin, prior education, employment, career plans) and opinions regarding graduate study. Number mailed, 361; number returned, 140.

Schedule X was sent to persons who received advanced degrees in economics in 1939-40 or 1949-50. Names and addresses of these persons were supplied by department chairmen who responded to Sched-

ules III and VI. A questionnaire was sent to every third person so listed. In addition, questionnaires were sent to all other persons who received the Ph.D. in 1939-40 or 1949-50 and who are members of the American Economic Association. The purpose of this schedule was similar to that of Schedule IX. Number mailed, 528; number returned, 218.

Schedule XI was sent to the chairmen of departments of economics in institutions which do *not* give graduate work and which have enrollments of 2,000 or more as shown in the *World's Almanac*. The purpose of this schedule was to obtain the opinions of these academic employers of economists regarding graduate education. Number mailed, 203; number returned, 89.

Schedule XII was sent to a small list of leading supervisors of economists in various agencies of the Federal Government. Its purpose was to obtain opinions of these persons regarding the training of economists. Number mailed, 48; number returned, 22.

Manuscripts and editorial correspondence relating to the regular quarterly issues of the REVIEW should be addressed to Bernard F. Haley, Managing Editor of THE AMERICAN ECONOMIC REVIEW, Stanford University, Stanford, California.

OTHER DEPARTMENTS

OLIVER MITCHELL WENTWORTH SPRAGUE

Thirty-ninth President of the American Economic Association, 1937

Oliver M. W. Sprague was born in Somerville, Massachusetts, April 22, 1873. He died in Boston on May 24, 1953.

He attended St. Johnsbury Academy in Vermont before entering Harvard College. From Harvard he received his B.A. degree, *summa cum laude*, in 1894, his A.M. in 1895, and his Ph.D. in 1897. (He was awarded Litt.D. degree by Columbia in 1938.) After a year of study in England, he returned to Harvard as an assistant in economics. He served as instructor 1900-04 and as assistant professor 1904-05, became professor of economics at the Imperial University in Japan in 1905; returned to the newly established Harvard Graduate School of Business Administration in 1908; and was appointed Edmund Cogswell Converse professor in 1913, which post he occupied until 1941, when he became professor *emeritus*.

From 1930-33, Professor Sprague was granted leave to serve as economic adviser to the Bank of England, and in the early months of the New Deal, he served as financial and executive assistant to the Secretary of the United States Treasury. At other times he was adviser to the Reichsbank, the Bank of France, the Bank for International Settlements, and the League of Nations.

As a member of the Gold Delegation of the League of Nations and in his subsequent advisory role, Professor Sprague participated in final efforts to maintain the gold standard. He split with the New Deal in November, 1933, over the best means of promoting economic recovery.

Professor Sprague's advice was also sought by private organizations. At the time of his death, he was director of the National Shawmut Bank of Boston and a member of the advisory board of the Massachusetts Investors Trust. Until shortly before his death he was also an adviser to the General Motors Corporation on foreign exchange problems.

When Professor Sprague served as President of the American Economic Association, he started an innovation in program planning for the annual meetings. With the exception of one session devoted to Marxian economics, the whole program (joint with the American Statistical Association) was centered on the general topic of savings and investment, the leitmotiv being expressed in the title of his presidential address, "The Recovery Problem in the United States."

Professor Sprague was a former president of the Harvard chapter of Phi Beta Kappa, a member of the American Academy of Arts and Sciences, and of the American Philosophical Society. He was the author of *History of Crises Under the National Banking System* (1910), *Banking Reform in the United States* (1911), *Theory and History of Banking* (1929), and *Recovery and Common Sense* (1934).

No. 39 of a series of past presidents of the Association.

O.M.W. Sprague

VOLUME XLIII DECEMBER, 1953 NUMBER FIVE, PART I

MATHEMATICAL, OR "LINEAR," PROGRAMMING: A NONMATHEMATICAL EXPOSITION

By ROBERT DORFMAN*

This paper is intended to set forth the leading ideas of mathematical programming[1] purged of the algebraic apparatus which has impeded their general acceptance and appreciation. This will be done by concentrating on the graphical representation of the method. While it is not possible, in general, to portray mathematical programming problems in two-dimensional graphs, the conclusions which we shall draw from the graphs will be of general validity and, of course, the graphic representation of multidimensional problems has a time-honored place in economics.

The central formal problem of economics is the problem of allocating scarce resources so as to maximize the attainment of some predetermined objective. The standard formulation of this problem—the so-called marginal analysis—has led to conclusions of great importance for the understanding of many questions of social and economic policy. But it is a fact of common knowledge that this mode of analysis has not recommended itself to men of affairs for the practical solution of their economic and business problems. Mathematical programming is based on a restatement of this same formal problem in a form which is designed to be useful in making practical decisions in business and economic affairs. That mathematical programming is nothing but a reformulation of the standard economic problem and its solution is the main thesis of this exposition.

The motivating idea of mathematical programming is the idea of a

* The author is associate professor of economics at the University of California, Berkeley.

[1] The terminology of the techniques which we are discussing is in an unsatisfactory state. Most frequently they are called "linear programming" although the relationships involved are not always linear. Sometimes they are called "activities analysis," but this is not a very suggestive name. The distinguishing feature of the techniques is that they are concerned with programming rather than with analysis, and, at any rate, "activities analy-

"process" or "activity." A process is a specific method for performing an economic task. For example, the manufacture of soap by a specified formula is a process. So also is the weaving of a specific quality of cotton gray goods on a specific type of loom. The conventional production function can be thought of as the formula relating the inputs and outputs of all the processes by which a given task can be accomplished.

For some tasks, *e.g.*, soap production, there are an infinite number of processes available. For others, *e.g.*, weaving, only a finite number of processes exist. In some cases, a plant or industry may have only a single process available.

In terms of processes, choices in the productive sphere are simply decisions as to which processes are to be used and the extent to which each is to be employed. Economists are accustomed to thinking in terms of decisions as to the quantities of various productive factors to be employed. But an industry or firm cannot substitute Factor A for Factor B unless it does some of its work in a different way, that is, unless it substitutes a process which uses A in relatively high proportions for one which uses B. Inputs, therefore, cannot be changed without a change in the way of doing things, and often a fundamental change. Mathematical programming focusses on this aspect of economic choice.

The objective of mathematical programming is to determine the optimal levels of productive processes in given circumstances. This requires a restatement of productive relationships in terms of processes and a reconsideration of the effect of factor scarcities on production choices. As a prelude to this theoretical discussion, however, it will be helpful to consider a simplified production problem from a common-sense point of view.

I. *An Example of Mathematical Programming*

Let us consider an hypothetical automobile company equipped for the production of both automobiles and trucks. This company, then, can perform two economic tasks, and we assume that it has a single process for accomplishing each. These two tasks, the manufacture of automobiles and that of trucks, compete for the use of the firm's facilities. Let us assume that the company's plant is organized into four departments: (1) sheet metal stamping, (2) engine assembly, (3) automobile final assembly, and (4) truck final assembly—raw materials, labor, and all other components being available in virtually unlimited amounts at constant prices in the open market.

The capacity of each department of the plant is, of course, limited. We assume that the metal stamping department can turn out sufficient stampings for 25,000 automobiles or 35,000 trucks per month. We can then calculate the combinations of automobile and truck stampings

which this department can produce. Since the department can accommodate 25,000 automobiles per month, each automobile requires 1/25,000 or 0.004 per cent of monthly capacity. Similarly each truck requires 0.00286 per cent of monthly capacity. If, for example, 15,000 automobiles were manufactured they would require 60 per cent of metal stamping capacity and the remaining 40 per cent would be sufficient to produce stampings for 14,000 trucks. Then 15,000 automobiles and 14,000 trucks could be produced by this department at full operation. This is, of course, not the only combination of automobiles and trucks which could be produced by the stamping department at full operation. In Figure 1, the line labeled "Metal Stamping" represents all such combinations.

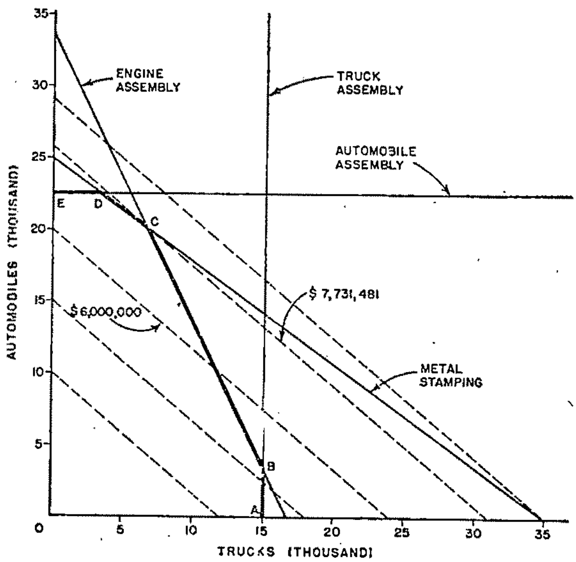

FIGURE 1. CHOICES OPEN TO AN AUTOMOBILE FIRM

Similarly we assume that the engine assembly department has monthly capacity for 33,333 automobile engines or 16,667 truck engines or, again, some combination of fewer automobile and truck engines. The combinations which would absorb the full capacity of the engine assembly department are shown by the "Engine Assembly" line in Figure 1. We assume also that the automobile assembly department can accommodate 22,500 automobiles per month and the truck assembly department 15,000 trucks. These limitations are also represented in Figure 1.

We regard this set of assumptions as defining two processes: the

production of automobiles and the production of trucks. The process of producing an automobile yields, as an output, one automobile and absorbs, as inputs, 0.004 per cent of metal stamping capacity, 0.003 per cent of engine assembly capacity, and 0.00444 per cent of automobile assembly capacity. Similarly the process of producing a truck yields, as an output, one truck and absorbs, as inputs, 0.00286 per cent of metal stamping capacity, 0.006 per cent of engine assembly capacity, and 0.00667 per cent of truck assembly capacity.

The economic choice facing this firm is the selection of the numbers of automobiles and trucks to be produced each month, subject to the restriction that no more than 100 per cent of the capacity of any department can be used. Or, in more technical phraseology, the choice consists in deciding at what level to employ each of the two available processes. Clearly, if automobiles alone are produced, at most 22,500 units per month can be made, automobile assembly being the effective limitation. If only trucks are produced, a maximum of 15,000 units per month can be made because of the limitation on truck assembly. Which of these alternatives should be adopted, or whether some combination of trucks and automobiles should be produced depends on the relative profitability of manufacturing trucks and automobiles. Let us assume, to be concrete, that the sales value of an automobile is $300 greater than the total cost of purchased materials, labor, and other direct costs attributable to its manufacture. And, similarly, that the sale value of a truck is $250 more than the direct cost of manufacturing it. Then the net revenue of the plant for any month is 300 times the number of automobiles produced plus 250 times the number of trucks. For example, 15,000 automobiles and 6,000 trucks would yield a net revenue of $6,000,000. There are many combinations of automobiles and trucks which would yield this same net revenue; 10,000 automobiles and 12,000 trucks is another one. In terms of Figure 1, all combinations with a net revenue of $6,000,000 lie on a straight line, to be specific, the line labelled $6,000,000 in the figure.

A line analogous to the one which we have just described corresponds to each possible net revenue. All these lines are parallel, since their slope depends only on the relative profitability of the two activities. The greater the net revenue, of course, the higher the line. A few of the net revenue lines are shown in the figure by the dashed parallel lines.

Each conceivable number of automobiles and trucks produced corresponds to a point on the diagram, and through each point there passes one member of the family of net revenue lines. Net revenue is maximized when the point corresponding to the number of automobiles and trucks produced lies on the highest possible net revenue line. Now the effect of the capacity restrictions is to limit the range of choice to

outputs which correspond to points lying inside the area bounded by the axes and by the broken line ABCDE. Since net revenue increases as points move out from the origin, only points which lie on the broken line need be considered. Beginning then with Point A and moving along the broken line we see that the boundary of the accessible region intersects higher and higher net revenue lines until point C is reached. From there on, the boundary slides down the scale of net revenue lines. Point C therefore corresponds to the highest attainable net revenue. At point C the output is 20,370 automobiles and 6,481 trucks, yielding a net revenue of $7,731,481 per month.

The reader has very likely noticed that this diagram is by no means novel. The broken line, ABCDE, tells the maximum number of automobiles which can be produced in conjunction with any given number of trucks. It is therefore, apart from its angularity, a production opportunity curve or transformation curve of the sort made familiar by Irving Fisher, and the slope of the curve at any point where it has a slope is the ratio of substitution in production between automobiles and trucks. The novel feature is that the production opportunity curve shown here has no defined slope at five points and that one of these five is the critical point. The dashed lines in the diagram are equivalent to conventional price lines.

The standard theory of production teaches that profits are maximized at a point where a price line is tangent to the production opportunity curve. But, as we have just noted, there are five points where our production opportunity curve has no tangent. The tangency criterion therefore fails. Instead we find that profits are maximized at a corner where the slope of the price line is neither less than the slope of the opportunity curve to the left of the corner nor greater than the slope of the opportunity curve to the right.

Diagrammatically, then, mathematical programming uses angles where standard economics uses curves. In economic terms, where does the novelty lie? In standard economic analysis we visualize production relationships in which, if there are two products, one may be substituted for the other with gradually increasing difficulty. In mathematical programming we visualize a regime of production in which, for any output, certain factors will be effectively limiting but other factors will be in ample supply. Thus, in Figure 1, the factors which effectively limit production at each point can be identified by noticing on which limitation lines the point lies. The rate of substitution between products is determined by the limiting factors alone and changes only when the designation of the limiting factors changes. In the diagram a change in the designation of the limiting factors is represented by turning a corner on the production opportunity curve.

We shall come back to this example later, for we have not exhausted its significance. But now we are in a position to develop with more generality some of the concepts used in mathematical programming.

II. *The Model of Production in Mathematical Programming*

A classical problem in economics is the optimal utilization of two factors of production, conveniently called capital and labor. In the usual analysis, the problem is formulated by conceiving of the two factors as cooperating with each other in accordance with a production function which states the maximum quantity of a product which can be obtained by the use of stated quantities of the two factors. One convenient means of representing such a production function is an "isoquant diagram," as in Figure 2. In this familiar figure, quantities of labor are plotted along the horizontal axis and quantities of capital

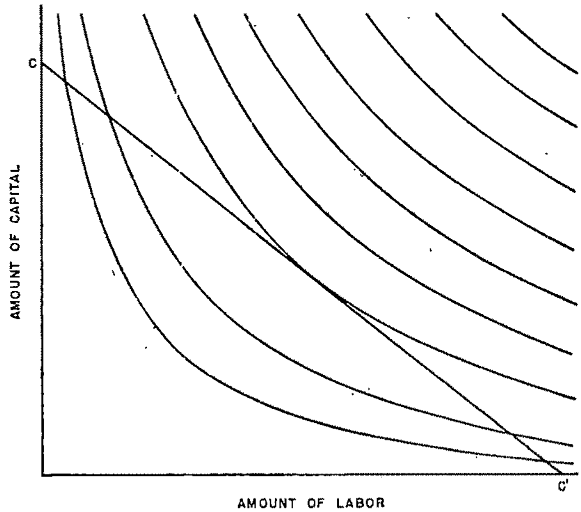

FIGURE 2. AN ISOQUANT DIAGRAM

along the vertical. Each of the arcs in the body of the diagram corresponds to a definite quantity of output, higher arcs corresponding to greater quantities.

If the prices per unit of capital and labor are known, the combinations of labor and capital which can be purchased for a fixed total expenditure can be shown by a sloping straight line like CC′ in the figure, the slope depending only on the relative prices. Two interpretations follow immediately. First, the minimum unit cost of producing the output represented by any isoquant can be achieved by using the combination of labor and capital which corresponds to the point where that

isoquant is tangent to a price line. Second, the greatest output attainable with any given expenditure is represented by the isoquant which is tangent to the price line corresponding to that expenditure.

This diagram and its analysis rest upon the assumption that the two factors are continuously substitutable for each other in such wise that if the amount of labor employed be reduced by a small amount it will be possible to maintain the quantity of output by a *small* increase in the amount of capital employed. Moreover, this analysis assumes that each successive unit decrement in the amount of labor will require a slightly larger increment in the amount of capital if output is to remain constant. Otherwise the isoquants will not have the necessary shape.

All this is familiar. We call it to mind only because we are about to develop an analogous diagram which is fundamental to mathematical programming. First, however, let us see why a new diagram and a new approach are felt to be necessary.

The model of production which we have just briefly sketched very likely is valid for some kinds of production. But for most manufacturing industries, and indeed all production where elaborate machinery is used, it is open to serious objection. It is characteristic of most modern machinery that each kind of machine operates efficiently only over a narrow range of speeds and that the quantities of labor, power, materials and other factors which cooperate with the machine are dictated rather inflexibly by the machine's built-in characteristics. Furthermore, at any time there is available only a small number of different kinds of machinery for accomplishing a given task. A few examples may make these considerations more concrete. Earth may be moved by hand shovels, by steam or diesel shovels, or by bulldozers. Power shovels and bulldozers are built in only a small variety of models, each with inherent characteristics as to fuel consumption per hour, number of operators and assistants required, cubic feet of earth moved per hour, etc. Printing type may be set by using hand-fonts, linotype machines or monotype machines. Again, each machine is available in only a few models and each has its own pace of operation, power and space requirements, and other essentially unalterable characteristics. A moment's reflection will bring to mind dozens of other illustrations: printing presses, power looms, railroad and highway haulage, statistical and accounting calculation, metallic ore reduction, metal fabrication, etc. For many economic tasks the number of processes available is finite, and each process can be regarded as inflexible with regard to the ratios among factor inputs and process outputs. Factors cannot be substituted for each other except by changing the levels at which entire technical processes are used, because each process uses factors in fixed characteristic ratios. In mathematical programming, accordingly, process substi-

tution plays a rôle analogous to that of factor substitution in conventional analysis.

We now develop an apparatus for the analysis of process substitution. For convenience we shall limit our discussion to processes which consume two factors, to be called capital and labor, and produce a single output. Figure 3 represents such a process. As in Figure 2, the horizontal axis is scaled in units of labor and the vertical axis in units of capital. The process is represented by the ray, OA, which is scaled in units of output. To each output there corresponds a labor requirement found by locating the appropriate mark on the process ray and reading straight down. The capital requirement is found in the same manner by reading straight across from the mark on the process line. Similarly, to each amount of labor there corresponds a quantity of out-

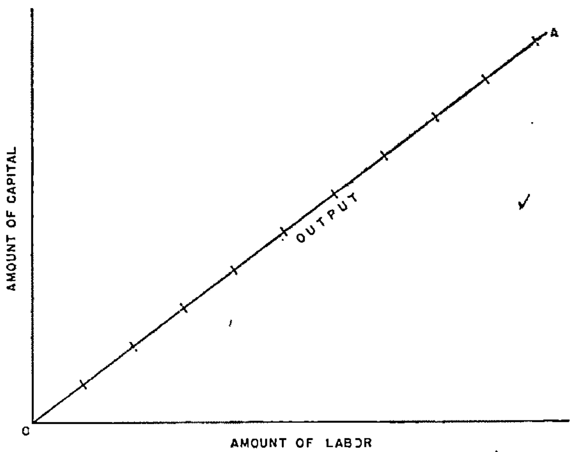

FIGURE 3. A PROCESS

put, found by reading straight up, and a quantity of capital, found by reading straight across from the output mark.

It should be noted that the quantity of capital in this diagram is the quantity used in a process rather than the quantity owned by an economic unit; it is capital-service rather than capital itself. Thus, though more or less labor may be combined with a given machine—by using it more or fewer hours—the ratio of capital to labor inputs, that is, the ratio of machine-hours to labor hours—is regarded as technologically fixed.

Figure 3 incorporates two important assumptions. The fact that the line OA is straight implies that the ratio between the capital input and the labor input is the same for all levels of output and is given, indeed, by the slope of the line. The fact that the marks on the output line are

evenly spaced indicates that there are neither economies nor diseconomies of scale in the use of the process, *i.e.*, that there will be strict proportionality between the quantity of output and the quality of either input. These assumptions are justified rather simply on the basis of the notion of a process. If a process can be used once, it can be used twice or as many times as the supplies of factors permit. Two linotype machines with equally skilled operators can turn out just twice as much type per hour as one. Two identical mills can turn out just twice as many yards of cotton per month as one. So long as factors are available, a process can be duplicated. Whether it will be economical to do so is, of course, another matter.

If there is only one process available for a given task there is not much scope for economic choice. Frequently, however, there will be

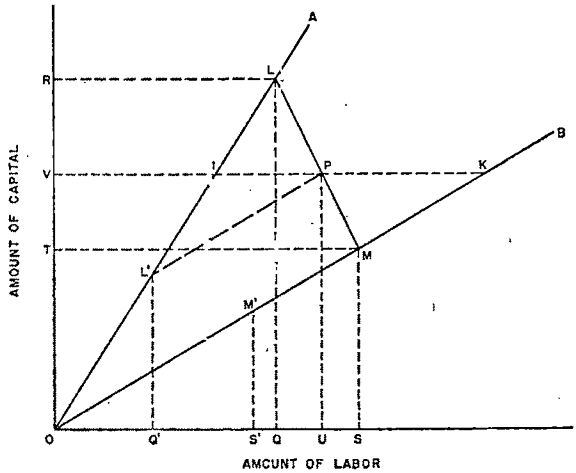

FIGURE 4. TWO PROCESSES

several processes. Figure 4 represents a situation in which two procedures are available, Process A indicated by the line OA and Process B indicated by OB. We have already seen how to interpret points on the lines OA and OB. The scales by which output is measured on the two rays are not necessarily the same. The scale on each ray reflects the productivity of the factors when used in the process represented by that ray and has no connection with the output scale on any other process ray. Now suppose that points L and M represent production of the same output by the two processes. Then LM, the straight line between them, will represent an isoquant and each point on this line will correspond to a combination of Processes A and B which produces the same output as OL units of Process A or OM units of Process B.

To see this, consider any point P on the line LM and draw a line

through P parallel to OB. Let L′ be the point where this line intersects OA. Finally mark the point M′ on OB such that OM′ = L′P. Now consider the production plan which consists of using Process A at level OL′ and Process B at level OM′.[2] It is easy to show that this production plan uses OU units of labor, where U is the labor coordinate of point P, and OV units of capital, where V is the capital coordinate of point P.[3]

Since the coordinates of point P correspond to the quantities of factors consumed by OL′ units of Process A and OM′ units of Process B, we interpret P as representing the combined production plan made up of the specified levels of the two processes. This interpretation implies an important economic assumption, namely, that if the two processes are used simultaneously they will neither interfere with nor enhance each other so that the inputs and outputs resulting from simultaneous use of two processes at any levels can be found by adding the inputs and outputs of the individual processes.

In order to show that P lies on the isoquant through points L and M it remains only to show that the sum of the outputs corresponding to points L′ and M′ is the same as the output corresponding to point L or point M. This follows at once from the facts that the output corresponding to any point on a process ray is directly proportional to the length of the ray up to that point and that the triangles LL′P and LOM in Figure 4 are similar.[4] Thus if we have two process lines like OA and OB and find points L and M on them which represent producing the same output by means of the two processes then the line segment connecting the two equal-output points will be an isoquant.

We can now draw the mathematical programming analog of the familiar isoquant diagram. Figure 5 is such a diagram with four process lines shown. Point M represents a particular output by use of Process A and points L, K, J represent that same output by means of Processes B, C, D, respectively. The succession of line segments connecting these

[2] An alternative construction would be to draw a line through point P parallel to OA. It would intersect OB at M′. Then we could lay off OL′ equal to M′P on OA. This would lead to exactly the same results as the construction used in the text. The situation is analogous to the "parallelogram of forces" in physics.

[3] Proof: Process A at level OL′ uses OQ′ units of labor, Process B at level OM′ uses OS′ units of labor, together they use OQ′ + OS′ units of labor. But, by construction, L′P is equal and parallel to OM′. So Q′U = OS′. Therefore, OQ′ + OS′ = OQ′ + Q′U = OU units of labor. The argument with respect to capital is similar.

[4] Proof: Let Output (X) denote the output corresponding to any point X, on the diagram. Then Output (M′)/Output (M) = OM′/OM and Output (L′)/Output (L) = OL′/OL. By assumption: Output (L) = Output (M). So Output (M′)/Output (L) = OM′/OM. Adding, we have:

$$\frac{\text{Output }(M') + \text{Output }(L')}{\text{Output }(L)} = \frac{OM'}{OM} + \frac{OL'}{OL} = \frac{L'P}{OM} + \frac{OL'}{OL} = \frac{L'L}{OL} + \frac{OL'}{OL} = 1.$$

four points is the isoquant for that same output. It is easy to see that any other succession of line segments respectively parallel to those of MLKJ is also an isoquant. Three such are shown in the figure. It is instructive to compare Figure 5 with Figure 2 and note the strong resemblance in appearance as well as in interpretation.

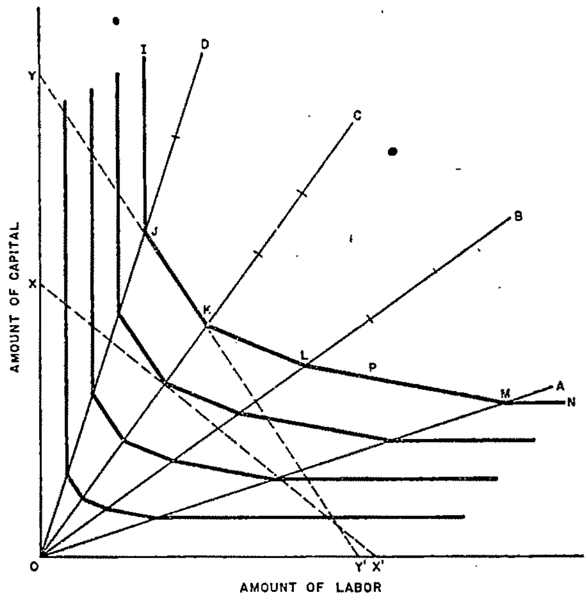

FIGURE 5. FOUR PROCESSES

We may draw price lines on Figure 5, just as on the conventional kind of isoquant diagram. The dashed lines XX′ and YY′ represent two possible price lines. Consider XX′ first. As that line is drawn, the maximum output for a given expenditure can be obtained by use of Process C alone, and, conversely, the minimum cost for a given output is also obtained by using Process C alone. Thus, for the relative price regime represented by XX′, Process C is optimal. The price line YY′ is drawn parallel to the isoquant segment JK. In this case Process C is still optimal, but Process D is also optimal and so is any combination of the two.

It is evident from considering these two price lines, and as many others as the reader wishes to visualize, that an optimal production program can always be achieved by means of a single process, which process depending, of course, on the slope of the price line. It should be noted, however, that the conventional tangency criterion is no longer applicable.

We found in Figure 5 that an optimal economic plan need never use

more than a single process for each of its outputs.[5] That conclusion is valid for the situation depicted, which assumed that the services of the two factors could be procured in any amounts desired at constant relative prices. This assumption is not applicable to many economic problems, nor is it used much in mathematical programming. We must now, therefore, take factor supply conditions into account.

III. *Factor Supplies and Costs*

In mathematical programming it is usual to divide all factors of production into two classes: unlimited factors, which are available in any amount desired at constant unit cost, and limited or scarce factors, which are obtainable at constant unit cost up to a fixed maximum quantity and thereafter not at all. The automobile example illustrates this classification. There the four types of capacity were treated as fixed factors available at zero variable cost; all other factors were grouped under direct costs which were considered as constant per unit of output.

The automobile example showed that this classification of factors is adequate for expressing the maximization problem of a firm dealing in competitive markets. In the last section we saw that when all factors are unlimited, this formulation can be used to find a minimum average cost point.

Both of these applications invoked restrictive assumptions and, furthermore, assumptions which conflict with those conventionally made in studying resource allocation. In conventional analysis we conceive that as the level of production of a firm, industry or economy rises, average unit costs rise also after some point. The increase in average costs is attributable in part to the working of the law of variable proportions,[6] which operates when the inputs of some but not all factors of production are increased. As far as the consequences of increasing some but not all inputs are concerned, the contrast between mathematical programming and the marginal analysis is more verbal than substantive. A reference to Figure 4 will show how such changes are handled in mathematical programming. Point J in Figure 4 represents the production of a certain output by the use of Process A alone. If it is desired to increase output without increasing the use of capital, this can be done by moving to the right along the dotted line JK, since this line cuts successively higher isoquants. Such a movement would correspond to using increasingly more of Process B and increasingly

[5] Recall, however, that we have not taken joint production into account nor have we considered the effects of considerations from the demand side.

[6] *Cf.* J. M. Cassels, "On the Law of Variable Proportions," in W. Fellner and B. F. Haley, eds., *Readings in the Theory of Income Distribution* (Philadelphia, 1946), pp. 103-18.

less of Process A and thus, indirectly, to substituting labor for capital. If, further, we assume that unit cost of production is lower for Process A than for Process B this movement would also correspond to increasing average cost of production. Thus both marginal analysis and mathematical programming lead to the same conclusion when factor proportions are changed: if the change starts from a minimum cost point the substitution will lead to gradually increasing unit costs.

But changing input proportions is only one part of the story according to the conventional type of analysis. If output is to be increased, any of three things may happen. First, it may be possible to increase the consumption of all inputs without incurring a change in their unit prices. In this case both mathematical programming and marginal analysis agree that output will be expanded without changing the ratios among the input quantities and average cost of production will not increase.[7] Second, it may not be possible to increase the use of some of the inputs. This is the case we have just analyzed. According to both modes of analysis the input ratios will change in this case and average unit costs will increase. The only difference between the two approaches is that if average cost is to be plotted against output, the marginal analyst will show a picture with a smoothly rising curve while the mathematical programmer will show a broken line made up of increasingly steep line segments. Third, it may be possible to increase the quantities of all inputs but only at the penalty of increasing unit prices or some kind of diseconomies of scale. This third case occurs in the marginal analysis, indeed it is the case which gives long-run cost curves their familiar shape, but mathematical programming has no counterpart for it.

The essential substantive difference we have arrived at is that the marginal analysis conceives of pecuniary and technical diseconomies associated with changes in scale while mathematical programming does not.[8] There are many important economic problems in which factor prices and productivities do not change in response to changes in scale or in which such variations can be disregarded. Most investigations of industrial capacity, for example, are of this nature. In such studies we seek the maximum output of an industry, regarding its inventory of physical equipment as given and assuming that the auxiliary factors needed to cooperate with the equipment can be obtained in the quanti-

[7] *Cf.* F. H. Knight, *Risk, Uncertainty and Profit* (Boston, 1921), p. 98.

[8] Even within the framework of the marginal analysis the concept of diseconomies of scale has been challenged on both theoretical and empirical grounds. For examples of empirical criticism see Committee on Price Determination, Conference on Price Research, *Cost Behavior and Price Policy* (New York, 1943). The most searching theoretical criticism is in Piero Sraffa, "The Laws of Returns under Competitive Conditions," *Econ. Jour.*, Dec. 1926, XXXVI, 535-50.

ties dictated by the characteristics of the equipment. Manpower requirement studies are of the same nature. In such studies we take both output and equipment as given and calculate the manpower needed to operate the equipment at the level which will yield the desired output. Studies of full employment output fall into the same format. In such studies we determine in advance the quantity of each factor which is to be regarded as full employment of that factor. Then we calculate the optimum output obtainable by the use of the factors in those quantities.

These illustrations should suffice to show that the assumptions made in mathematical programming can comprehend a wide variety of important economic problems. The most useful applications of mathematical programming are probably to problems of the types just described, that is, to problems concerned with finding optimum production plans using specified quantities of some or all of the resources involved.

IV. *Analysis of Production with Limited Factors*

The diagrams which we have developed are readily adaptable to the analysis of the consequences of limits on the factor supplies. Such limits are, of course, the heart of Figure 1 where the four principal lines represent limitations on the process levels which result from limits on the four factor quantities considered. But Figure 1 cannot be used when more than two processes have to be considered. For such problems diagrams like Figures 3, 4, and 5 have to be used.

Figure 6 reproduces the situation portrayed in Figure 5 with some

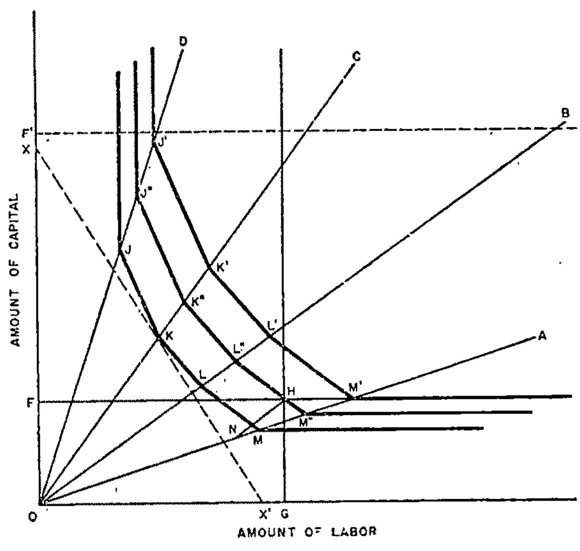

FIGURE 6. FOUR PROCESSES, WITH LIMITATIONS

additional data to be explained below. Let OF represent the maximum amount of capital which can be used and thus show a factor limitation. The horizontal line through F divides the diagram into two sections: all points above the line correspond to programs which require more capital than is available; points on and below the line represent programs which do not have excessive capital requirements. This horizontal line will be called the capital limitation line. Points on or below it are called "feasible," points above it are called "infeasible."

The economic unit portrayed in Figure 6 has the choice of operating at any feasible point. If maximum output is its objective, it will choose a point which lies on the highest possible isoquant, *i.e.*, the highest isoquant which touches the capital limitation line. This is the one labelled J′K′L′M′, and the highest possible output is attained by using Process A.

Of course, maximum output may not be the objective. The objective may be, for example, to maximize the excess of the value of output over labor costs. We shall refer to such an excess as a "net value." The same kind of diagram can be used to solve for a net value provided that the value of each unit of output is independent of the number of units produced[9] and that the cost of each unit of labor is similarly constant. If these provisos are met, each point on a process ray will correspond to a certain physical output but also to a certain value of output, cost of labor, and net value of output. Further, along any process ray the net value of output will equal the physical output times the net value per unit and will therefore be proportional to the physical output. We may thus use a diagram similar to Figure 6 except that we think of net value instead of physical output as measured along the process rays and we show isovalue line instead of isoquants. This has been done on Figure 7, in which the maximum net value attainable is the one which corresponds to the isovalue contour through point P, and is attained by using Process C.

It should be noted in both Figures 6 and 7 that the optimal program consisted of a single process, that shifts in the quantity of capital available would not affect the designation of the optimal process though they would change its level, and that the price lines, which were crucial in Figure 5, played no rôle.

The next complication, and the last one we shall be able to consider, is to assume that both factors are in limited supply. This situation is portrayed in Figure 6 by adding the vertical line through point G to represent a labor limitation. The available quantity of labor is shown, of course, by the length OG. Then the points inside the rectangle

[9] This is a particularly uncomfortable assumption. We use it here to explain the method in its least complicated form.

OFHG represent programs which can be implemented in the sense that they do not require more than the available supplies of either factor. This is the rectangle of feasible programs. The greatest achievable output is the one which corresponds to the highest isoquant which touches the rectangle of feasible programs. This is the isoquant J″K″L″M″, and furthermore, since the maximum isoquant touches the rectangle at H, H represents the program by which the maximum output can be produced.

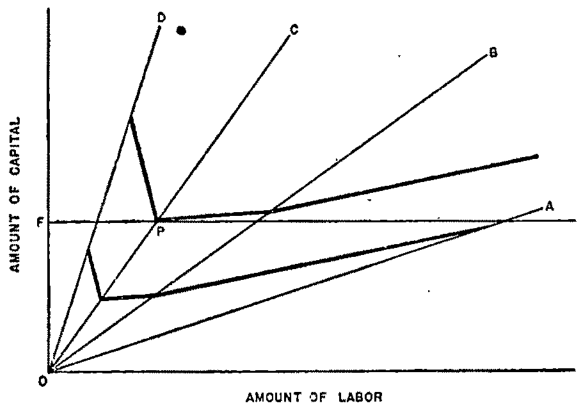

FIGURE 7. FOUR PROCESSES WITH ISOVALUE LINES

This solution differs from the previous ones in that the solution-point does not lie on any process ray but between the rays for Processes A and B. We have already seen that a point like H represents using Process A at level ON and Process B at level NH.

Two remarks are relevant to this solution. First: with the factor limitation lines as drawn, the maximum output requires two processes. If the factor limitation lines had been drawn so that they intersected exactly on one of the process rays, only one process would have been required. If the factor limitation lines had crossed to the left of Process D or to the right of Process A, the maximizing production plan would require only one process. But, no matter how the limitation lines be drawn, at most two processes are required to maximize output. We are led to an important generalization: maximum output may always be obtained by using a number of processes which does not exceed the number of factors in limited supply, if this number is greater than zero. The conclusions we drew from Figures 6 and 7 both conform to this rule, and it is one of the basic theorems of mathematical programming.

Second: although at most two processes are required to obtain the maximum output, which two depends on the location of the factor limits. As shown, the processes used for maximum output were Proces-

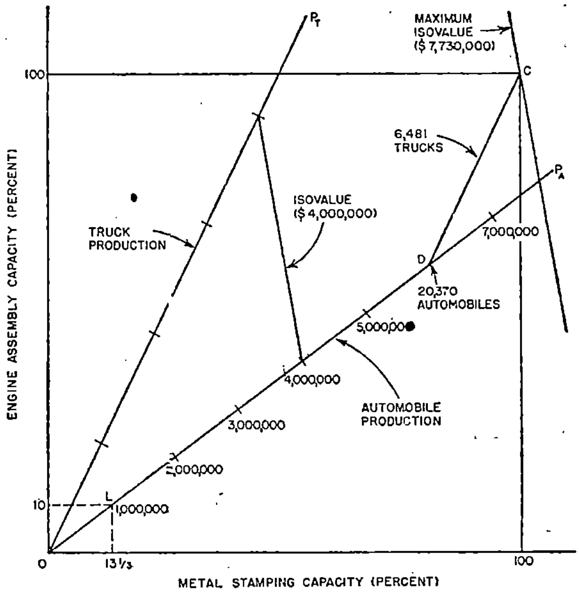

FIGURE 8. AUTOMOBILE EXAMPLE, OPTIMAL PLAN

ses A and B. If somewhat more capital, represented by the amount OF′, were available, the maximizing processes would have been Processes C and D. If two factors are limited, it is the ratio between their supplies rather than the absolute supplies of either which determines the processes in the optimum program. This contrasts with the case in which only one factor is limited. Just as the considerations which determine the optimum set of processes are more complicated when two factors are limited than when only one is, so with three or more limited factors the optimum conditions become more complicated still and soon pass the reach of intuition. This, indeed, is the *raison d'être* of the formidable apparatus of mathematical programming.

We can make these considerations more concrete by applying them to the automobile example. Referring to Figure 1, (p. 799), we note that the optimum production point, C, lay on the limitation lines for engine assembly and metal stamping, but well below the limits for automobile and truck assembly. The limitations on automobile and truck assembly capacity are, therefore, ineffective and can be disregarded. The situation in terms of the two effectively limiting types of capacity is shown in Figure 8.

In Figure 8 the ray P_A represents the process of producing automobiles and P_T the process of producing trucks. These two processes can be operated at any combination of levels which does not require the use of more than 100 per cent of either metal stamping or engine assembly

capacity. Thus the rectangle in the diagram is the region of feasible production programs. The optimal production program is the one in the feasible region which corresponds to the highest possible net revenue.[10] Thus it will be helpful to construct isorevenue lines, as we did in Figure 7. To do this, consider automobile production first. Each point on P_A corresponds to the production of a certain number of automobiles per month. Suppose, for example, that the scale is such that point L represents the production of 3,333 automobiles per month. It will be recalled that each automobile yields a net revenue of $300. Therefore, 3,333 automobiles yield a revenue of $1,000,000. Point L, then, corresponds to a net revenue of $1,000,000 as well as to an output of 3,333 automobiles per month. Since (see page 799), 3,333 automobiles require 13⅓ per cent of metal stamping capacity and 10 per cent of engine assembly capacity, the coordinates of the $1,000,000 net revenue point on P_A are established at once. By a similar argument, the point whose coordinates are 26⅔ per cent of metal stamping capacity and 20 per cent of engine capacity is the $2,000,000 net revenue point on P_A. In the same manner, the whole ray can be drawn and scaled off in terms of net revenue, and so can P_T, the process ray for truck production. The diagram is completed by connecting the $4,000,000 points on the two process lines in order to show the direction of the isorevenue lines.

The optimum program is at point C, where the two capacity limits intersect, because C lies on the highest isorevenue line which touches the feasible region. Through point C we have drawn a line parallel to the truck production line and meeting the automobile production line at D. By our previous argument, the length OD represents the net revenue from automobile production in the optimal program and the length DC represents the net revenue from trucks. If these lengths be scaled off, the result, of course, will be the same as the solution found previously.

V. *Imputation of Factor Values*

We have just noted that the major field of application of mathematical programming is to problems where the supply of one or more factors of production is absolutely limited. Such scarcities are the genesis of value in ordinary analysis, and they generate values in mathematical programming too. In fact, in ordinary analysis the determination of outputs and the determination of prices are but two aspects of the same problem, the optimal allocation of scarce resources. The same is true in mathematical programming.

[10] Since the objective of the firm is, by assumption, to maximize revenue rather than physical output, we may consider automobile and truck production as two alternative processes for producing revenue instead of as two processes with disparate outputs.

Heretofore we have encountered prices only as data for determining the direct costs of processes and the net value of output. But of course the limiting factors of production also have value although we have not assigned prices to them up to now. In this section we shall see that the solution of a mathematical programming problem implicitly assigns values to the limiting factors of production. Furthermore, the implicit pricing problem can be solved directly and, when so solved, constitutes a solution to the optimal allocation problem.

Consider the automobile example and ask: how much is a unit (1 per cent) of each of the types of capacity worth to the firm? The approach to this question is similar in spirit to the familiar marginal analysis. With respect to each type of capacity we calculate how much the maximum revenue would increase if one more unit were added, or how much revenue would decrease if one unit were taken away. Since there is a surplus of automobile assembly capacity, neither the addition nor the subtraction of one unit of this type would affect the optimum program or the maximum net revenue. Hence the value of this type of capacity is nil. The analysis and result for truck assembly are the same.

We find, then, that these two types of capacity are free goods. This does not imply that an automobile assembly line is not worth having, any more than, to take a classic example, the fact that air is a free good means that it can be dispensed with. It means that it would not be worth while to increase this type of capacity at any positive price and that some units of these types could be disposed of without loss.

The valuation of the other types of capacity is not so trivial. In Figure 9 possible values per per cent of engine assembly capacity are scaled along the horizontal axis and values per per cent of metal stamping capacity are scaled along the vertical axis. Now consider any possible pair of values, say engine assembly capacity worth \$20,000 per unit and metal stamping worth \$40,000. This is represented by point A on the figure. Applying these values to the data on pages 798-99, the values of capacity required for producing an automobile is found to be: $(0.004 \times \$40{,}000) + (0.003 \times \$20{,}000) = \$220$ which is well under the value of producing an automobile, or \$300.[11] In the same way, if engine assembly capacity is worth \$60,000 per per cent of capacity and metal stamping capacity is valued at \$30,000 per unit (point B), the cost of scarce resources required to produce an automobile will be exactly equal to the value of the product. This is clearly not the only combination of resource values which will precisely absorb the value of output when the resources are used to produce automobiles. The automobile production line in the figure, which passes through point B, is

[11] These unit values are also marginal values since costs of production are constant.

the locus of all such value combinations. A similar line has been drawn for truck production to represent those combinations of resource values for which the total value of resources used in producing trucks is equal to the value of output. The intersection of these two lines is obviously the only pair of resource values for which the marginal resource cost of producing an additional automobile is equal to the net value of an automobile and the same is true with respect to trucks. The pair can be found by plotting or, with more precision, by algebra. It is found that 1 per cent of engine assembly capacity is worth $9,259 and 1 per cent of metal stamping capacity is worth $68,056.

To each pair of values for the two types of capacity, there corresponds a value for the entire plant. Thus to the pair of values represented by point A there corresponds the plant value of (100 × $20,000) + (100 × $40,000) = $6,000,000. This is not the only pair of resource values which give an aggregate plant value of $6,000,000. Indeed, any pair of resource values on the dotted line through A corresponds to the same aggregate plant value. (By this stage, Figure 9 should become strongly reminiscent of Figure 1, page 799.) We have drawn a number of dotted lines parallel to the one just described, each corresponding to a specific aggregate plant value. The dotted line which passes through the intersection of the two production lines is of particular interest. By measurement or otherwise this line can be found to correspond to a plant value of $7,731,500 which, we recall, was found to be the maximum attainable net revenue.

Let us consider the implications of assigning values to the two limiting factors from a slightly different angle. We have seen that as soon as unit values have been assigned to the factors an aggregate value is assigned to the plant. We can make the aggregate plant value as low as we please, simply by assigning sufficiently low values to the various factors. But if the values assigned are too low, we have the unsatisfactory consequence that some of the processes will give rise to unimputed surpluses. We may, therefore, seek the lowest aggregate plant value which can be assigned and still have no process yield an unimputed surplus. In the automobile case, that value is $7,731,500. In the course of finding the lowest acceptable plant value we find specific unit values to be assigned to each of the resources.

In this example there are two processes and four limited resources. It turns out that only two of the resources were effectivly limiting, the others being in relatively ample supply. In general, the characteristics of the solution to a programming problem depend on the relationship between the number of limited resources and the number of processes taken into consideration. If, as in the present instance, the number of limited resources exceeds the number of processes it will usually turn

out that some of the resources will have imputed values of zero and that the number of resources with positive imputed values will be equal to the number of processes.[12] If the number of limited resources equals the number of processes all resources will have positive imputed values. If, finally, the number of processes exceeds the number of limited resources, some of the processes will not be used in the optimal program. This situation, which is the usual one, was illustrated in Figure 6. In this case the total imputed value of resources absorbed will equal net revenue for some processes and will exceed it for others. The number of

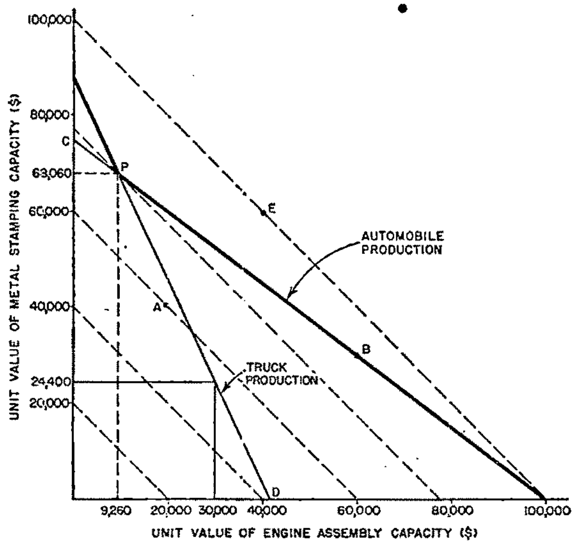

FIGURE 9. AUTOMOBILE EXAMPLE, IMPLICIT VALUES

processes for which the imputed value of resources absorbed equals the net revenue will be just equal to the number of limited resources and the processes for which the equality holds are the ones which will appear at positive levels in the optimal program. In brief, the determination of the minimum acceptable plant value amounts to the same thing as the determination of the optimal production program. The programming problem and the valuation problem are not only closely related, they are basically the same.

This can be seen graphically by comparing Figures 1 and 9. Each figure contains two axes and two diagonal boundary lines. But the boundary lines in Figure 9 refer to the same processes as the axes in Figure 1, and the axes in Figure 9 refer to the same resources as the

[12] We say "usually" in this sentence because in some special circumstances the number of resources with positive imputed values may exceed the number of processes.

diagonal boundary lines in Figure 1. Furthermore, in using Figure 1 we sought the net revenue corresponding to the highest dashed line touched by the boundary; in using Figure 9 we sought the aggregate value corresponding to the lowest dashed line which has any points on or outside the boundary; and the two results turned out to be the same. Formally stated, these two figures and the problems they represent are *duals* of each other.

The dualism feature is a very useful property in the solution of mathematical programming problems. The simplest way to see this is to note that when confronting a mathematical programming problem we have the choice of solving the problem or its dual, whichever is easier. Either way we can get the same results. We can use this feature now to generalize our discussion somewhat. Up to now when dealing with more than two processes we have had to use relatively complicated

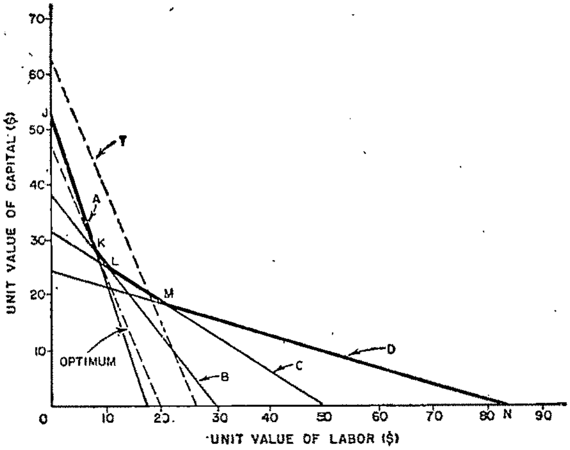

FIGURE 10. THE VALUATION PROBLEM, FOUR PROCESSES

diagrams like Figure 6 because straightforward diagrams like Figure 1 did not contain enough axes to represent the levels of the processes. Now we can use diagrams modeled on Figure 9 to depict problems with any number of processes so long as they do not involve more than two scarce factors. Figure 10 illustrates a diagram for four processes and is, indeed, derived from Figure 6. In Figure 10 line A represents all pairs of factor values such that Process A would yield neither a profit nor a loss. Lines B, C, and D are similarly interpreted. The dashed line T is a locus along which the aggregate value of the labor and capital available to the firm (or industry) is constant. Its position is not relevant to the analysis; its slope, which is simply the ratio of the quantity of available labor to that of capital, is all that is significant. The broken

line JKLMN divides the graph into two regions. All points on or above it represent pairs of resource values such that no process gives rise to an unimputed surplus. Let us call this the acceptable region. For each point below that broken line there is at least one process which does have an unimputed surplus. This is the unacceptable region. We then seek for that point in the acceptable region which corresponds to the lowest aggregate plant value. This point will, of course, give the set of resource values which makes the accounting profit of the firm as great as possible without giving rise to any unimputed income. The point which meets these requirements is K, and a dotted line parallel to T has been drawn through it to indicate the minimum acceptable aggregate plant value.

At point K Processes A and B yield zero profits, and Processes C and D yield losses. Hence Processes A and B are the ones which should be used, exactly as we found in Figure 6. To be sure, this diagram does not tell the levels at which A and B should be used, any more than Figure 6 tells the valuations to be placed on the two resources. But finding the levels after the processes have been selected is a comparatively trivial matter. All that is necessary is to find the levels which will fully utilize the resources which are not free goods. This may be done algebraically or by means of a diagram like Figure 8.

VI. *Applications*

In the first section we asserted that the principal motivation of mathematical programming was the need for a method of analysis which lent itself to the practical solution of the day-to-day problems of business and the economy in general. Immediately after making that claim we introduced a highly artificial problem followed by a rather extended discussion of abstract and formal relationships. The time has now come to indicate the basis for saying that mathematical programming is a practical method of analysis.

The essential simplification achieved in mathematical programming is the replacement of the notion of the production function by the notion of the process. The process is a highly observable unit of activity and the empirical constants which characterize it can be estimated without elaborate analysis. Furthermore in many industries the structure of production corresponds to operating a succession of processes, as we have conceived them. Many industrial decisions, like shutting down a bank of machines or operating an extra shift, correspond naturally to our concept of choosing the level of operation of a process. In brief, mathematical programming is modelled after the actual structure of production in the hope that thereby it will involve only observable

constants and directly controllable variables.

Has this hope been justified? The literature already contains a report of a successful application to petroleum refining.[13] I have made a similar application which, perhaps, will bear description. The application was to a moderate-sized refinery which produces premium and regular grades of automotive gasoline. The essential operation studied was blending. In blending, ten chemically distinct kinds of semirefined oil, called blending stocks, are mixed together. The result is a saleable gasoline whose characteristics are approximately the weighted average of the characteristics of the blending stocks. For example, if 500 gallons of a stock with octane rating of 80 are blended with 1,000 gallons of a stock with octane rating of 86 the result will be $500 + 1{,}000 = 1{,}500$ gallons of product with octane rating of $(\frac{1}{3} \times 80) + (\frac{2}{3} \times 86) = 84$.

The significant aspect of gasoline blending for our present purposes is that the major characteristics of the blend—its knock rating, its vapor pressure, its sulphur content, etc.—can be expressed as linear functions of the quantities of the various blending stocks used. So also can the cost of the blend if each of the blending stocks has a definite price per gallon. Thus the problem of finding the minimum cost blend which will meet given quality specifications is a problem in mathematical programming.

Furthermore, in this refinery the quantities of some of the blending stocks are definitely limited by contracts and by refining capacity. The problem then arises: what are the most profitable quantities of output of regular and premium gasoline, and how much of each blending stock should be used for each final product. This problem is analogous to the artificial automobile example, with the added complication of the quality specifications. The problem is too complicated for graphic analysis but was solved easily by arithmetical procedures. As far as is known, mathematical programming provides the only way for solving such problems. Charnes and Cooper have recently published the solution to a similar problem which arose in the operations of a metalworking firm.[14]

An entirely different kind of problem, also amenable to mathematical programming, arises in newsprint production. Freight is a major element in the cost of newsprint. One large newsprint company has six mills, widely scattered in Canada, and some two hundred customers, widely scattered in the United States. Its problem is to decide how much

[13] A. Charnes, W. W. Cooper and B. Mellon, "Blending Aviation Gasolines," *Econometrica* Apr. 1952, XX, 135-59.

[14] A. Charnes, W. W. Cooper, and Donald Farr and Staff, "Linear Programming and Profit Preference Scheduling for a Manufacturing Firm," *Jour. Operations Research Society of America,* May 1953, I, 114-29.

newsprint to ship from each mill to each customer so as, first, to meet the contract requirements of each customer, second, to stay within the capacity limits of each mill, and third, to keep the aggregate freight bill as small as possible. This problem involves 1,200 variables (6 mills $\times$ 200 customers), in contrast to the two or four variable problems we have been discussing. In the final solution most of these variables will turn out to be zero—the question is which ones. This problem is solved by mathematical programming and, though formidable, is not really as formidable as the count of variables might indicate.

These few illustrations should suffice to indicate that mathematical programming is a practical tool for business planning. They show, also, that it is a flexible tool because both examples deviated from the format of the example used in our exposition. The petroleum application had the added feature of quality specification. In the newsprint application there were limits on the quantity of output as well as on the quantities of the inputs. Nevertheless mathematical programming handled them both easily.

On the other hand, it should be noted that both of these were small-scale applications, dealing with a single phase of the operation of a single firm. I believe that this has been true of all successful applications to date. Mathematical programmers are still a long way from solving the broad planning problem of entire industries or an entire economy. But many such broad problems are only enlarged versions of problems which have been met and solved in the context of the single firm. It is no longer premature to say that mathematical programming has proved its worth as a practical tool for finding optimal economic programs.

VII. *Conclusion*

Our objective has been only to introduce the basic notions of mathematical programming and to invest them with plausibility and meaning. The reader who would learn to solve a programming problem—even the simplest—will have to look elsewhere,[15] though this paper may serve as a useful background.

Although methods of solution have been omitted from this exposition, we must emphasize that these methods are fundamental to the whole concept of mathematical programming. Some eighty years ago Walras conceived of production in very much the same manner as mathematical

[15] The standard reference is T. C. Koopmans, ed., *Activity Analysis of Production and Allocation* (New York, 1951). Less advanced treatments may be found in A. Charnes, W. W. Cooper, and A. Henderson, *An Introduction to Linear Programming* (New York, 1953); and my own *Application of Linear Programming to the Theory of the Firm* (Berkeley, 1951).

programmers, and more recently A. Wald and J. von Neumann used this view of production and methods closely allied to those of mathematical programming to analyze the conditions of general economic equilibrium.[16] These developments, however, must be regarded merely as precursors of mathematical programming. Programming had no independent existence as a mode of economic analysis until 1947 when G. B. Dantzig announced the "simplex method" of solution which made practical application feasible.[17] The existence of a method whereby economic optima could be explicitly calculated stimulated research into the economic interpretation of mathematical programming and led also to the development of alternative methods of solution. The fact that economic and business problems when formulated in terms of mathematical programming can be solved numerically is the basis of the importance of the method. The omission of methods of solution from this discussion should not, therefore, be taken to indicate that they are of secondary interest.

We have considered only a few of the concepts used in mathematical programming and have dealt with only a single type of programming problem. The few notions we have considered, however, are the basic ones; all the rest of mathematical programming is elaboration and extension of them. It seems advisable to mention two directions of elaboration, for they remove or weaken two of the most restrictive assumptions which have here been imposed.

The first of these extensions is the introduction of time into the analysis. The present treatment has dealt with a single production period in isolation. But in many cases, successive production periods are interrelated. This is so, for example, in the case of a vertically integrated firm where the operation of some processes in one period is limited by the levels of operation in the preceding period of the processes which supply their raw materials. Efficient methods for analyzing such "dynamic" problems are being investigated, particularly by George Dantzig.[18] Although the present discussion has been static, the method of analysis can be applied to problems with a time dimension.

[16] Walras' formulation is in *Éléments d'économie politique pure ou théorie de la richesse sociale,* 2d ed. (Lausanne, 1889), 20^e Leçon. The contributions of A. Wald and J. von Neumann appeared originally in *Ergebnisse eines mathematischen Kolloquiums,* Nos. 6, 7, 8. Wald's least technical paper appeared in *Zeitschrift für Nationalökonomie,* VII (1936) and has been translated as "On some Systems of Equations of Mathematical Economics," *Econometrica,* Oct. 1951, XIX, 368-403. Von Neumann's basic paper appeared in translation as "A Model of General Economic Equilibrium," *Rev. Econ. Stud.,* 1945-46, XIII, 1-9.

[18] "A Note on a Dynamic Leontief Model with Substitution" (abstract), *Econometrica,* Jan. 1953, XXI, 179.

The second of these extensions is the allowance for changes in the prices of factors and final products. In our discussion we regarded all prices as unalterable and independent of the actions of the economic unit under consideration. Constant prices are, undeniably, a great convenience to the analyst, but the method can transcend this assumption when necessary. The general mathematical theory of dealing with variable prices has been investigated[19] and practical methods of solution have been developed for problems where the demand and supply curves are linear.[20] The assumption of constant prices, perhaps the most restrictive assumption we have made, is adopted for convenience rather than from necessity.

Mathematical programming has been developed as a tool for economic and business planning and not primarily for the descriptive, and therefore predictive, purposes which gave rise to the marginal analysis. Nevertheless it does have predictive implications. In so far as firms operate under the conditions assumed in mathematical programming it would be unreasonable to assume that they acted as if they operated under the conditions assumed by the marginal analysis. Consider, for example, the automobile firm portrayed in Figure 1. How would it respond if the price of automobiles were to fall, say by $50 a unit? In that case the net revenue per automobile would be $250, the same as the net revenue per truck. Diagrammatically, the result would be to rotate the lines of equal revenue until their slope was 45 degrees. After this rotation, point C would still be optimum and this change in prices would cause no change in optimum output. Mathematical programming gives rise, thus, to a kinked supply curve.

On the other hand, suppose that the price of automobiles were to rise by $50. Diagrammatically this price change would decrease the steepness of the equal revenue lines until they were just parallel to the metal stamping line. The firm would then be in a position like that illustrated by the YY′ line in Figure 5. The production plans corresponding to points on the line segment DC in Figure 1 would all yield the same net revenue and all would be optimal. If the prices of automobiles were to rise by more than $50 or if a $50 increase in the price of automobiles were accompanied by any decrease in the price of trucks, the point of optimal production would jump abruptly from point C to point D.

Thus mathematical programming indicates that firms whose choices

[19] See H. W. Kuhn and A. W. Tucker, "Non-Linear Programming," in J. Neyman, ed., *Proceedings of the Second Berkeley Symposium on Mathematical Statistics and Probability* (Berkeley, 1951), pp. 481-92.

[20] I reported one solution of this problem to a seminar at the Massachusetts Institute of Technology in September 1952. Other solutions may be known.

are limited to distinct processes will respond discontinuously to price variations: they will be insensitive to price changes over a certain range and will change their levels of output sharply as soon as that range is passed. This theoretical deduction surely has real counterparts.

The relationship between mathematical programming and welfare economics is especially close. Welfare economics studies the optimal organization of economic effort; so does mathematical programming. This relationship has been investigated especially by Koopmans and Samuelson.[21] The finding, generally stated, is that the equilibrium position of a perfectly competitive economy is the same as the optimal solution to the mathematical programming problem embodying the same data.

Mathematical programming is closely allied mathematically to the methods of input-output analysis or interindustry analysis developed largely by W. W. Leontief.[22] The two methods were developed independently, however, and it is important to distinguish them conceptually. Input-output analysis finds its application almost exclusively in the study of general economic equilibrium. It conceives of an economy as divided into a number of industrial sectors each of which is analogous to a process as the term is used in mathematical programming. It then takes either of two forms. In "open models" an input-output analysis starts with some specified final demand for the products of each of the sectors and calculates the level at which each of the sector-processes must operate in order to meet this schedule of final demands. In "closed models" final demand does not appear but attention is concentrated on the fact that the inputs required by each sector-process must be supplied as outputs by some other sector-processes. Input-output analysis then calculates a mutually compatible set of output levels for the various sectors. By contrast with mathematical programming the conditions imposed in input-output analysis are sufficient to determine the levels of the processes and there is no scope for finding an optimal solution or a set of "best" levels. To be sure, input-output analysis can be regarded as a special case of mathematical programming in which the number of products is equal to the number of processes. On the other hand, the limitations on the supplies of resources which play so important a rôle in mathematical programming are not dealt with explicitly in input-output analysis. On the whole it seems

[21] T. C. Koopmans, "Analysis of Production as an Efficient Combination of Activities," in T. C. Koopmans, ed., *op. cit.*, pp. 33-97; P. A. Samuelson, "Market Mechanisms and Maximization" (a paper prepared for the Rand Corp., 1949).

[22] W. W. Leontief, *The Structure of American Economy 1919-1939*, 2nd. ed. (New York, 1951).

best to regard these two techniques as allied but distinct methods of analysis addressed to different problems.)

Mathematical programming, then, is of significance for economic thinking and theory as well as for business and economic planning. We have been able only to allude to this significance. Indeed, apart from the exploration of welfare implications, very little thought has been given to the consequences for economics of mathematical programming because most effort has been devoted to solving the numerous practical problems to which it gives rise. The outlook is for fruitful researches into both the implications and applications of mathematical programming.

VERTICAL EQUILIBRIUM UNDER PURE QUALITY COMPETITION

By LAWRENCE ABBOTT*

The customary approach to equilibrium analysis is through the construction of a "pure" model consisting of a simplified market situation in which competing sellers offer products whose quality is uniform and unchanging, so that equilibrating adjustments are restricted to changes in price and output. The usefulness of such a model lies in the fact that, by ruling out both quality variability and imperfect substitution, the analyst is able to abstract completely from the quality element in exchange, and can therefore obtain the clearest possible picture of the price variable.

This so-called "purely competitive" situation, however, is not the only pure type of competitive market. Another "pure" and "competitive" model precisely the reverse of the one just described may be set up, in which the *price* of all competing goods in the market is uniform and unchanging, while quality is freely variable, so that adjustments are restricted to changes in product quality—with, of course, corresponding changes in output. To distinguish such a situation from its more familiar counterpart, we shall find it convenient to label it *pure quality competition*. The term *pure price competition* can then be used to describe the opposite ("purely competitive") situation, in which the price variable operates in isolation.

This second "pure" model is, of course, neither new nor unfamiliar. Chamberlin's path-breaking analysis of "product equilibrium" in *The Theory of Monopolistic Competition* employed this very model. But despite the highly suggestive character of that analysis, the study of quality competition as an equilibrating process has remained a neglected area of economic theory.[1]

* The author is associate professor of economics at Union College.

[1] Analyses of spatial competition by Hotelling, Smithies and others have thrown some light on the subject, but are restricted to only one aspect of quality competition. A recent analysis of product competition in the broadcasting industry by Peter O. Steiner, employing a different technique in dealing with the same general problem, offers interesting possibilities for analysis of quality competition; yet Steiner's model likewise treats quality variability in only a limited way, since variation is confined to choice between "types" of radio programs (quiz show, comedy program, etc.), within each of which quality variation is implicitly assumed to be nil or of no effect on listener preference ("Program Patterns

Yet the limiting case of "pure quality competition" is surely of great importance. Markets which approximate it—characterized by price rigidity or stickiness and by products which are not fixed in quality—form a substantial fraction of today's economy. Analysis of "pure quality competition" is also important because it provides an analytical device of great usefulness in the study of free markets in general. By stilling the movements of price, we are enabled to observe with greater clarity the kinds of behavior and adjustment *other than price and output changes* which are found in markets where both products and prices are free to vary. These kinds of behavior are especially significant in the many markets in which prices, although not completely rigid, move sluggishly.

This paper is an attempt to provide a theoretical framework in which this important but neglected aspect of competition can be usefully studied. Its specific objective is to determine the conditions of equilibrium with respect to one aspect of quality only in a hypothetical single-fixed-price market in which quality is freely variable. Its scope is therefore severely limited. Nevertheless, it is hoped that the analysis will throw some light on the kinds of behavior and market structures that quality competition tends to produce, and may pave the way for the construction of more comprehensive theoretical models.

I. *Definitions of Terms*

The word *quality* will be used in its broadest sense, to describe any or all of the various qualitative characteristics of a physical product or service, or combination of the two, offered for sale. "Quality" thus includes materials, design, style, location of a retail outlet—in short, any and every qualitative attribute. Quality is therefore a multidimensional variable—a compound of numerous elements (*e.g.*, in a necktie: size, shape, type of construction, pattern, color scheme, material, texture, durability, resistance to wrinkling, color fastness), each of which is variable.

Quality competition will refer to producers' independent actions regarding the quality of their respective products, prompted by the desire to improve their positions, when such products are variable in quality and are offered in the same market.

The *market* is defined as embracing those products which are com-

---

and Preferences, and the Workability of Competition in Radio Broadcasting," *Quart. Jour. Econ.*, May 1952, LXVI, 194-223). Another recent theoretical study of greater comprehensiveness is Hans Brems' *Product Equilibrium under Monopolistic Competition* (Cambridge, 1951), but this work contains no thoroughgoing analysis of the equilibrium positions of firms in markets where quality alone is variable.

petitive in the sense of being substitutable alternatives, each capable of serving some given purpose, or, let us say, performing some given function, or rendering some given service, or enabling its possessor to engage in some given activity. In other words, products will be considered to belong within the same market or industry if they can be regarded as variable means to some definable common end.[2]

For our purposes it will be convenient to distinguish three kinds of quality variability:

1. *Vertical*—the kind of quality change or comparison which may properly be described in terms of "higher" or "lower." Two things distinguish this kind: (a) the "superior" of any two qualities is considered preferable by virtually all buyers, and (b) it entails greater cost. Therefore an upward (or downward) vertical change in quality unaccompanied by a change in price gives the buyer more (or less) for his money than before.

Vertical differences in quality frequently consist of differences in the quantity of some desired ingredient or attribute: the metallic content of an ore, the tensile strength of steel wire, the mileage in an automobile tire. The simplest kind of vertical variation is a change in the size of the unit. With vertical differences it is appropriate to speak of one quality being "better" or of higher "grade" than another, of "cheap" versus "good" quality, and of "improvement" or "deterioration" of quality.

2. *Horizontal*—those differences about which there is no clear-cut agreement. Two things distinguish this type: (a) different people will rank dissimilar qualities in different orders, and (b) cost differences, if any, are purely incidental. The existence of this category depends on the fact that people differ in their circumstances, values, and tastes. With differences of this sort we may properly speak of one quality being "more suitable" or "more appealing" than another, but such a statement is meaningful only if made with reference to a particular buyer or group of buyers. The most obvious examples of horizontal differences are those that involve aesthetic considerations: color, texture, shape, styling. Unlike vertical quality, horizontal quality is of a sort that can become excessive (*e.g.*, the stiffness of the springs of a mat-

[2] While this may not be a wholly rigorous definition of a market's boundaries, it seems acceptable enough for our purposes, especially if employed with an admixture of common sense. We may think of the toilet soap market, for example, as including only those products which can be used in a bathroom to cleanse the skin. Similarly, the furnace or space-heating-equipment market is limited to those products which keep buildings warm in winter. Ruby T. Norris presents this concept of an industry in *The Theory of Consumer's Demand* (New Haven, 1941), pp. 78-79. See also James S. Duesenberry, *Income, Saving, and the Theory of Consumer Behavior* (Cambridge, Mass., 1949), p. 20.

tress, or the hardness of a soft-boiled egg). Horizontal differences are, as a rule, nonmeasurable.[3]

3. *Innovational*—the introduction of a novel quality which is judged superior by most or all buyers, and which either costs no more to produce or is well worth whatever additional cost is involved, so that the older quality must eventually become obsolete. This kind of quality change, associated with innovation and progress, leads to "improved" rather than "higher" quality. A new idea having universal or near-universal appeal (*e.g.*, the three-passenger front seat) or a technical improvement in design (*e.g.*, steel-shafted golf clubs) lie in this category. Here the superiority is not due to better materials or workmanship, nor does the change alter the grade or price class to which a product belongs, but rather creates quality differences and improvement within each grade. Innovational change in quality, if considered an improvement, eventually makes obsolete the previously accepted quality, whereas differences in vertical quality, being accompanied by cost and price differences, show no tendency to be eliminated.

Actual quality changes do not always fit neatly into one or another of these three categories. A change may be a hybrid, such as innovational-horizontal, or may contain elements of all three, or may be innovational with respect to some horizontal qualities but not with respect to others. The above classification is simply an analytical device, imperfect yet highly useful for detailed analysis of quality competition.

II. *The Principal Assumptions*

In analyzing quality equilibrium, simplifying assumptions are of course needed. Moreover, it seems desirable to reduce the complexity of our task by restricting our scrutiny for the present to one aspect of quality variation. In the model here developed three important simplifications will be made:

(1) Innovational variation will be ruled out. Although this exclusion is made with some reluctance, since quality adjustments in the real

[3] The fact that some qualities are neither "better" nor "worse" than others, but merely better suited to some people's wants (and less suited to others') seems so self-evident that the statement presented above may be deemed superfluous. Yet the idea needs emphasizing since economists have so frequently written as if all significant quality differences were of the vertical type. See for example Marshall, *Principles of Economics*, 8th ed. (London, 1920), pp. 100, 113; Stephen Enke, "Profit Maximization under Monopolistic Competition," *Am. Econ. Rev.*, June 1941, XXXI, p. 322; M. W. Reder, *Studies in the Theory of Welfare Economics* (New York, 1947), p. 74.

The related idea that quality differences always involve cost differences has also been expressed from time to time. See E. H. Chamberlin, *The Theory of Monopolistic Competition*, 5th ed. (Cambridge, Mass., 1946), p. 96; Joan Robinson, *The Economics of Imperfect Competition* (London, 1933), p. 90 n.

world are to a large extent innovational in character, to attempt to incorporate innovational changes in a model concerned with quality equilibrium would raise enormous analytical difficulties. Human ingenuity is capable of devising countless variations of products. Progress in science and technology opens up ever new opportunities for further variation. Even in an economy in which people's wants remain constant, the number of moves and countermoves needed for the achievement of quality equilibrium would seem to be indefinitely great. To make our analysis manageable, we must impose conditions under which equilibrium is conceptually attainable within a reasonably short period.

The assumption that no innovational variation in quality occurs does not rule out all pioneer quality changes; two sorts remain possible. A new quality may be selected "in between" the qualities of two variants already in existence. (If bicycles of 24-inch and 26-inch wheels are already being produced, producers are free to offer a 25-inch bicycle.) And in the typical case in which a product's quality is compounded of numerous variable elements, existing quality elements may be put together in new combinations.[4]

(2) Since it seems advisable for the sake of brevity to confine this essay in model-building to one kind of quality adjustment, the consequences of *horizontal* variability will be assumed rather than deduced from other assumptions.[5] Accordingly, the model constructed below will show only the equilibrating *vertical* quality adjustments made in a one-fixed-price market. The following set of assumptions about horizontal quality differences and adjustments will be made: (a) Each firm's product differs horizontally from every other and attracts its own group of buyers. (b) Buyers' preferences and producers' choices of horizontal quality are such that, in the absence of vertical quality differences, the demand for every variety is the same, and therefore all firms have equal outputs. (c) When firms enter or leave the industry, horizontal quality adjustments take place in such a way that the above condition continues to hold.

(3) Vertical variability will be restricted to a single dimension, and conceived to be of such a character that the possible varieties can be arranged in order, in an "array" or "spectrum." More specifically, it will be assumed that vertical quality is variable in only one respect, is continuously variable, and is such that for every level of quality there is

[4] See Norris, *op. cit.*, p. 187: "In most commodity clusters, by taking thought one can perceive numerous rearrangements of existing qualitative differences, which are not offered."

[5] In a more comprehensive study of pure quality competition it would certainly be desirable to deduce the step-by-step process of horizontal adaptation and the position of horizontal equilibrium under various hypothetical conditions, in order that firms' behavior with regard to horizontal variability be explained rather than merely assumed.

a different, and only one, corresponding cost function.

This restriction enables us to depict quality levels graphically by drawing their corresponding cost curves. In reality, of course, product quality is likely to consist of numerous variable components, both horizontal and vertical; in fact, it is the multidimensional character of quality that makes choice between quality alternatives so much more difficult than choice between price alternatives. But when a product is vertically variable in several respects, the level of quality is conceivable only as some kind of average of the levels of the various vertical quality components, and the relationship between cost and vertical quality is obscure. The above simplification removes this difficulty.

Assumptions are also needed with regard to the way in which vertical quality variation affects demand. Two situations must be distinguished: one, in which vertical quality changes are made by all firms in unison; and the other, in which one firm raises or lowers quality while the rest of the firms leave quality unaltered.

Let us consider first market demand as a function of quality height when vertical quality changes are made simultaneously by all firms. Unless demand is totally inelastic, a rise in vertical quality in a fixed-price market—like a fall in price in a fixed-quality market—will affect the amount demanded to some degree. Buyers will purchase more. Yet the statement just made is ambiguous; does it mean that they will buy more units of the product? or merely that they will purchase enough to bring them more satisfaction? This question does not arise in the theory of price, since when products remain unchanged in quality an increase in satisfaction can be obtained only by an increase in the number of units consumed. But when quality is vertically variable, this is no longer true.

Suppose a situation in which mining companies are supplying ore to a copper-refining firm, and now offer a higher-grade ore at the same price. Will the refining firm increase its purchases? If the demand for refined copper is not totally inelastic, the firm will certainly buy a large enough quantity to give it a greater volume of refined copper, but it is altogether possible that a smaller volume of the superior ore will yield the increased volume of copper desired, in which case the firm's purchases of ore will actually be reduced. A similar pattern of response is possible in cases where the desired ingredient is not a physical substance like copper, but a psychic quantity or a measurable service, such as mileage in an automobile tire. In all such cases it is necessary to distinguish between the *volume of satisfaction* desired by the buyer and the *number of units* desired.

To obtain the sharpest picture of buyers' response to a vertical

change in quality, let us consider the kind of vertical variation in which an upward change increases the amount of satisfaction obtainable from a product, in the opinion of all buyers, without there being any accompanying decrease in its satisfactoriness in some other respect. Ordinarily a cost-raising quality change involves both a quantitative element (the giving of "more" of something which is invariably preferred in larger rather than smaller amounts) and a qualitative element (the provision of some other quality or qualities which are preferred in some optimum amount, and can be deficient or excessive).[6] Thus it is ordinarily a mixture, an alloy. But the proportions of the amalgam are variable, and we can conceive of a limiting case in which only the quantitative element is present—when the change consists simply of an alteration of the size of the unit, all sizes being equally convenient or economical, or of the amount of some desired ingredient contained in it, buyers being wholly indifferent to any concomitant variation in the amounts of other ingredients present.

If we restrict our analysis to this "purest" kind of vertical variation, the pattern of response of consumers to vertical changes can be stated without difficulty. Clearly it must be exactly what their pattern of response would be to price changes in terms of a fixed unit. In any market demand schedule which embraces the gamut between the prohibitive price and the zero price, there is at least one point or range of output (and price or prices) at which the price elasticity of demand is unity; at smaller outputs (higher prices) the elasticity is greater than one, while at larger outputs (lower prices) it is less than one. Similarly, in a fixed-price market in which the unit is of variable size there must be some range of small sizes in which an increase in the unit's size causes a rise in physical volume demanded which is more than proportional to the increase—in other words, it causes a rise in the number of units demanded; beyond this there must be a size, or series or range of sizes, in which an increase raises the physical volume demanded proportionally, so that the number of units demanded remains unchanged; and beyond that must lie another range in which, though the physical volume rises further, the number of units demanded declines as the unit grows in size until finally, at the satiation point, the decline in units demanded is proportional to the increase in the unit's size.

We need not, however, include the entire gamut of demand in our analysis. Just as, in price analysis, profit-maximizing or money-revenue-

[6] Even changes in the size of the unit involve more than a simple quantitative change if the product is packaged. Imagine, for instance, tomato juice being made available to housewives in cans of various sizes ranging between one ounce and one ton, all selling at the same price (resale being prohibited). Surely the "best buy" would be some size smaller than the biggest.

maximizing firms would never be concerned with prices in that lower range in which the elasticity of demand is unity or less than unity, so, in vertical quality analysis, we can safely ignore the corresponding upper range of vertical quality, since cost-raising quality improvement would not be advantageous to firms in a fixed-price market unless it induced an increase in the number of units sold. In what follows, therefore, we need be concerned only with that range of outputs in which a rise in quality results in a rise in sales, and vice versa. We shall assume (4) that output demanded is an increasing function of the height of a product's quality, and that all buyers, no matter what their horizontal preferences are, behave similarly in response to a given degree of quality improvement.

If all firms should raise (or lower) quality in unison, there would be no reason to expect any firm to gain (or lose) more or less than its proportionate share of the total increase (or decrease) in market demand. On the other hand, if one firm should make its product vertically superior to rival products, it could be expected to attract buyers previously attached to those rival products—and vice versa. We may reasonably assume, therefore, that (5) when vertical quality changes are made "across the board" each firm continues to maintain its former share of the market; when one firm alters quality while others do not, its share of the market changes in the same direction.

This raises the question as to whether vertical quality differences would be allowed to persist in a one-price market. Though this is obviously a question of considerable theoretical interest, the temptation to explore it will be resisted. It will simply be assumed that (6) every change in vertical quality made by a firm will be matched, either immediately or eventually, by all other firms. (This could be true either because whenever one firm is prompted to alter quality vertically, others are similarly prompted for the same reason, or alternatively, because other firms feel forced to follow suit in order to retain their shares of the market.)

This assumption further narrows our field of inquiry. It may be defended on the ground that it is in keeping with the conclusion generally reached in monopolistic competition theory that when sellers of differentiated products have identical costs, every variety must sell at the same price in equilibrium.

A few other assumptions are needed to keep the analysis manageable: (7) Each firm offers only one variety of the product. (8) Decisions of rival firms in matters of quality are made independently. There is no collusion. (9) Buyers act rationally and respond promptly and correctly to every change in the quality alternatives made available to them. (This condition bars producers from being able to exploit consumer

ignorance, apathy, and gullibility.) (10) All horizontal qualities cost the same to produce. (11) At any given output rate, cost varies with quality height; and at any given quality height, cost varies with output, in such a way that all average cost curves are U-shaped. (12) Cost functions do not change; technology is constant.

III. *Short-Run Equilibrium*

We are now ready to build a theoretical model of a market conforming to our definition of pure quality competition, and to study the equilibrating vertical quality adjustments made and the position of vertical equilibrium reached under certain assumed conditions.

The assumptions stated above will be used without modification throughout the analysis. Three additional assumptions are made at the start, then later modified: (13a) Firms seek to maximize profits. (14a) Every change in vertical quality is immediately matched by all other firms, and each firm acts on the expectation that this will be so. (In other words, we are assuming here that the already-assumed "eventual" elimination of vertical differences occurs so quickly, and that this fact is so well recognized, that no firm considers it worth while to seek the temporary benefits of a newly created differential.) (15a) The number of firms is fixed at ten.[7]

Let costs—which are similar for every firm—be as shown in Figure 1. Each of the curves labeled AC depicts the average cost of producing a certain level of quality, designated by the subscript. Since vertical quality is continuously variable, the family of cost curves drawn represents only a few of the possible heights of quality.

Let OP represent the fixed price, and AC_0 the cost curve applicable to the vertical quality currently being offered. Let the market demand for this quality at this price be such that every firm's demanded output (one-tenth of the market demand) is OM. We thus start our analysis with each firm earning only normal profits—the position that would be attained if vertical quality were held fixed and the number of firms allowed to vary until excess profits or losses were eliminated. Let firms now be free to vary quality vertically. Our problem is: what variation will occur?

In order to investigate this question, we need further information about demand: namely, the change in quantity demanded associated with each change in the level of quality. This information can be assembled in the form of a schedule, and plotted as a curve; but it will

[7] Use of numbers rather than algebraic symbols to designate the number of sellers is solely for convenience in exposition, and is not to be regarded as diminishing the model's generality. If the reader prefers, n can be substituted for 10, $n+1$ for 11, etc.

not be the familiar kind of demand curve showing quantity demanded as a function of price. Instead, it will show quantity demanded as a function of quality height, or, more precisely, of the cost uniquely associated with that height of quality at that rate of output.

Let us imagine the vertical quality to be varied while price is left unchanged, and note with respect to each quality height the output demanded, and also the unit cost of supplying that output. For each quality selected a point on our diagram can be found, the x distance of which represents the quantity demanded (the number of firms being what it is) and the y distance the unit cost of supplying that quantity. The locus of points so obtained is the desired curve.

This curve is sufficiently unconventional to warrant some further comments as to its character. It is, in a sense, a demand curve; for it

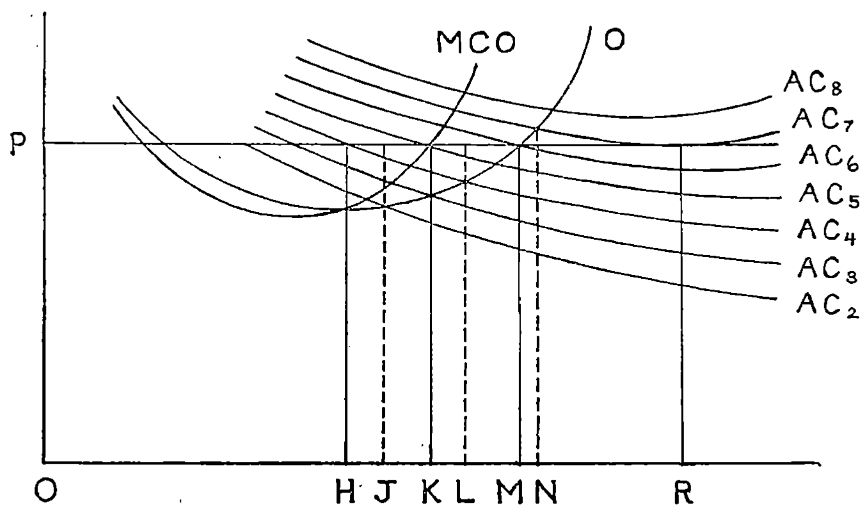

FIGURE 1

shows, for each height of quality selected (represented by the cost of supplying that quality), the quantity demanded. But it differs from the ordinary demand curve in that it does not give the demand *price* but rather the demand *cost* at each rate of output—that is the cost which the firm must incur in order to induce the purchase of that output, price being held at a predetermined level.

Its usefulness lies in the fact that it reveals the various options actually open to producers in a fixed-price market. In a "purely competitive" market the conventional average cost curve indicates genuine options. There each producer is at liberty to market as large or as small an output as he pleases; the cost curve and price line are useful in that together they reveal the consequences of each possible decision, and so

show which options are less desirable than others. But in a fixed-price market in which products differ horizontally in quality the conventional average cost curve does not contain options actually open to producers. All but one of the cost-output combinations on the curve are unattainable as long as the buyers' demand functions, the price, and the number of firms remain as they are. The producer is not free to unload on the market any output he chooses of a given level of quality; only if he varies vertical quality to the extent necessary to induce buyers to purchase the output he has in mind does that output become a genuine option. And then it is the cost of producing *that quality* which is the relevant cost in weighing the desirability of adjusting output to that rate. Hence the curve just described, relating demanded output to the cost of supplying that output, serves precisely the same purpose in a fixed-price market which the conventional cost curve serves in a fixed-quality market.

Since it reveals the cost of each of the actual options open to producers, this curve will be termed the *cost of options* curve, or, more briefly, the *options* curve.

Referring back to Figure 1, suppose that if quality AC_2 is selected, each firm's share of the resulting market will be OJ; if AC_3 is selected, demanded output will be OK; if AC_4 is selected, OL; and if AC_7 is selected, ON. The curve O, drawn in conformity with these suppositions, shows the possible choices open to the firm.

What shape should an options curve have? If average cost curves were horizontal lines, the options curve would climb continuously upward, showing an increase in unit cost associated with each rise in quality. But since average cost curves are assumed to be U-shaped, a complication arises: vertical variation influences cost in two different ways. On the one hand it alters the cost associated with any given output—that is, it shifts the average cost curve bodily. Its effect along this channel is always the same: a rise in quality means a rise in the cost function, and vice versa. But vertical quality change also alters the actual rate of output (except when the elasticity of demand is unity), so that the unit cost becomes different from what it would have been if output had not been affected. In other words, it causes a movement along the curve. And its effect along this channel is not always the same. Up to a point a rise in quality brings an increase in sales that makes possible economies resulting in a lower unit cost compared with the cost of the same quality produced at the lesser rate; but this effect gradually diminishes in force as output is increased until there finally comes a point where diseconomies arise that raise the unit cost of producing a given quality. Thus for a while the two influences pull against each other; and it is likely that at very low rates of output the

added cost of producing a higher quality will be more than offset by the reduced cost of producing on a larger scale. At such rates unit cost falls as quality is raised, and the options curve has a negative slope. But eventually the two influences reinforce each other, and unit cost must certainly change in the same direction as quality; the options curve then becomes positively sloped, and continues so until that height of quality is reached at which quality raising no longer raises output, when the curve becomes vertical. At still higher quality levels it bends backward.

If a family of U-shaped cost curves were drawn one directly above the other, it would be geometrically possible to draw an options curve which bent more and more in a counterclockwise direction until it showed unit cost falling once more as quality rose to very high levels. But this would be an improbable situation. It should be expected that when quality rises the average cost curve not only rises but shrinks toward the left. In the limiting case in which changes in vertical quality are merely changes in an accounting unit, the minimum-cost output rate must vary inversely with the size of the unit. In that case the locus of minimum points of the family of average cost curves would be a rectangular hyperbola, and no decline in output short of an actual decline in physical volume would keep the options curve from rising.

Since quality reduction is not advantageous unless it reduces unit cost, and quality raising is not advantageous unless it increases demand, we can confine our analysis to that range of vertical variation in which both unit cost and output vary positively with quality, thus ignoring the negatively sloped portions of the options curve.

It must be borne in mind that the position and shape of the options curve vary with the number of firms in the industry. This is because the firm's demanded output at each quality level varies with the number of firms, whereas its average cost curve relevant to each quality remains fixed. Therefore the firm's options curve shrinks upward and toward the left as new firms enter the industry. This complication will be dealt with shortly, when the number of firms is permitted to vary.

Now let us apply the options curve concept to the problem in hand. Under the assumed demand conditions it would not pay the firm to raise quality. At any output larger than OM, cost is higher than price. Quality reduction would be profitable, however. Any one of the four levels AC_2, AC_3, AC_4, and AC_5 would be an improvement. What level will be most profitable? The answer is found by drawing a *marginal cost of options* curve, showing for each rate of output the increment in total cost necessitated by a rise in quality sufficient to expand salable output by one unit. The point at which the marginal-cost-of-options curve intersects the price line denotes the output (and the quality

associated with it) that maximizes profit. This is shown in Figure 1, the marginal curve being labeled MCO. It can be seen that every firm will select OK of quality AC_8. With a change to this new level super-normal profits are earned.

IV. *Long-Run Equilibrium*

We now relax assumption 15a, substituting 15b: The number of firms is allowed to vary. Profits invite entry. When an eleventh firm enters, each firm's demand shrinks to one-eleventh of the market demand.[8] Its output, let us say, is now in the neighborhood of OJ; the firm is in disequilibrium once more. The options curve drawn in Figure 1 no longer holds. In order to determine the equilibrating adjustment needed, a new curve must be plotted, appropriate to an eleven-firm industry. In fact, we need at this point to visualize a whole family of options curves, one for each of the possible number of firms.

How should such a family be drawn? If we think of the options curve as composed of points, each of which lies on some AC curve associated with some level of quality, a new firm's entry causes these points to slide clockwise along their respective AC curves sufficiently so that each point is the same fraction of its former distance from the vertical axis. For each number of sellers these points lie differently and a separate options curve can be drawn.

None of the curves will intersect another; for when the number of firms increases, each point of the newly formed curve must lie somewhere to the left of the corresponding point (*i.e.*, the point representing the same height of quality) on the old one. And since the AC curves are concave from above, and descend more steeply than the options curve, and rise less steeply, each point on the options curve near its right extremity will move downward and to the left when a new firm enters, but the slope of its path will be less steep than the slope of the options curve at that point, while each point near the left extremity will move *upward* and to the left, and the slope of its path will be steeper than the slope of the options curve at that point. Therefore any new options curve formed by the entry of an additional firm must lie wholly within the area bounded by the former options curve.

The curves will also converge as we follow them upward to the left,

[8] It does not necessarily shrink to ten-elevenths of its former demand. A somewhat smaller shrinkage is to be expected, since there is an offsetting factor. Entry of a new firm causes products to be "spaced closer together" horizontally, which may be presumed to reduce their horizontal unsatisfactoriness on the average, and thus to increase the market demand. But so long as market demand grows less than sufficiently to offset completely the shrinkage in the firm's percentage of the market, the firm's demand will become smaller. This must now be assumed to be the case.

since they cannot cross the y axis but must continually approach it. And they will also converge as we follow them upward to the right, since each curve in the family must approach the limiting output at which the product must be given away free (or its size made infinitely great if the price remains fixed) and this limit must also be the y axis, *i.e.*, an infinitely small number of units.

The family of options curves appropriate to our model is shown in Figure 2. In this diagram O_{10} corresponds to the O of Figure 1, and MCO_{10} to MCO, the subscript 10 indicating a ten-firm industry.

The new output rate is shown in Figure 2 by the intersection of AC_4 and the new options curve O_{11}. It will be profitable for each firm to move to the right along O_{11} (*i.e.*, raise quality) until it reaches an

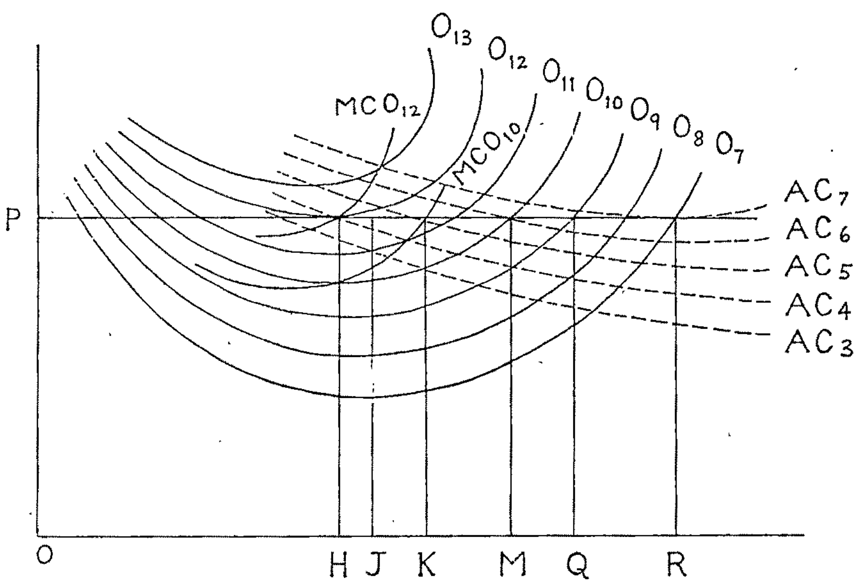

FIGURE 2

output at which its new marginal-cost-of-options curve (not shown) intersects the price line. As O_{11} has been drawn, excess profits will continue to be earned. These will attract further entry, which will cause a further shrinkage in output per firm, which will induce firms to adjust quality upward still more; and this process must continue until excess profits are eliminated. Curve O_{12} is drawn to illustrate the final equilibrium position. With twelve firms in the industry OH is the equilibrium rate of output, and AC_4 the equilibrium height of quality. Thus we see that long-run equilibrium is reached when the options curve shifts

upward and to the left (as new firms enter) until it becomes tangent to the price line.

This is the maximum number of firms (and varieties) possible in the industry. If a thirteenth firm entered, there would be no possible way by which firms could avoid losses.

V. *Alternative Equilibrium Situations*

Different equilibrium positions are reached if assumptions (13a) and (14a) are altered. Suppose, instead of (14a), we assume (14b): Each firm expects the vertical quality of all rival varieties to remain unaltered although actually, since all firms are faced with similar conditions and behave similarly, all firms make identical decisions as to vertical quality. Now the firm's actions are based on the belief that any given cheapening of quality results in a greater loss of sales than before, and any given quality betterment in a greater gain in sales. The options curve concept can be retained, but new curves would have to be drawn, indicating, for each industry-wide level of quality and for each number of sellers, the sales volume which the firm would secure by each vertical change if other firms kept quality unaltered.

This is a more complex situation. For each number of sellers in the industry, a family of options curves is needed, each of which intersects the "industry-wide options curve" (the curve shown in Figure 1) at the point at which the quality of the firm's product is the same as that of the rest of the industry. Let us imagine, in the situation depicted in Figure 1, that one firm varies quality while all other firms adhere to quality AC_6. How should the options curve appropriate to this supposition be drawn? It would intersect the price line where the AC_6 curve intersects it, but it would be a flatter curve—it would intersect the AC_5 curve, for example, further to the left, and the AC_7 curve further to the right—and would be tilted more to the right, so that its minimum point would lie further to the right.

Provided that the newly drawn curve were not so tilted as to be tangent to the price line, it would show the profitability of the firm's reducing quality to some lesser extent—to AC_5, say. Since all other firms likewise reduce quality to AC_5, the firm finds that its output has not shrunk as much as had been anticipated; their action has shifted the firm's options curve downward and toward the right so that it intersects the AC_5 curve at the point where the industry-wide options curve in Figure 1 intersects it. Further quality reduction is now worth while. By a succession of such adjustments the industry reaches its short-run equilibrium, with some excess profits being earned, and entry of new firms invited.

The process of reaching long-run equilibrium involves similar adjustments. These need not be described here in detail. It is sufficient to point out that because of the tiltedness of the options curves (as compared to the industry-wide curves shown in Figure 2), tangency to the price line will be achieved before the number of firms is increased to twelve so that in the final equilibrium quality will be higher than AC_4 and the number of firms fewer than twelve.

Now let us replace the profit-maximizing assumption (13a) with (13b): Firms desire no more (and no less) than an average return on investment, but always prefer a larger to a smaller volume of sales. Their objective is thus output maximization, subject to the condition that average cost does not exceed price.[9] In this case, contraction of output through quality reduction for the sake of temporary profit will be avoided. Expansion of output through quality raising is also undesirable so long as the number of firms remains unchanged, since it entails losses. But if we suppose that each firm believes that a rise in quality will force some competitor out of the market, and is willing to pay a temporary price for eventual gains in sales, quality raising will occur.

If firms, producing OM of AC_6 in a ten-firm industry (see Figure 2) raise quality to the level at which their new cost curve intersects the price line at, say, an output of OQ, and if the market demand should be nine times this output when quality is at that height, sales would temporarily fall short of OQ and losses would be incurred until one firm left the industry; then the remaining nine would earn the "normal" rate of return once more, and on an increased volume of sales. This process would continue either until the minimum point on an average cost curve were reached, or, if that point could not be reached in an industry of more than one firm, until the number of firms were reduced to one. According to Figure 1, a seven-firm industry could produce quality AC_7 at the minimum average cost rate, OR. Here equilibrium is reached. This is the maximum height of quality that can be produced and sold at price OP without incurring losses.

If firms sought to maximize output, yet were unwilling to undergo temporary losses for the sake of growth, no firm would follow this aggressive policy, but would adjust quality to the height at which the unit cost of producing the quality demanded equaled the price. Thus OM would be one of several possible long-run equilibrium positions.

[9] This assumption emphasizes the empire-building aspirations rather than the monetary appetites of business leaders. The writer will not take the space to defend its realism here. For justification, see J. A. Schumpeter, *Theory of Economic Development* (Cambridge, Mass., 1934), p. 93; R. A. Gordon, *Business Leadership in the Large Corporation* (Washington, 1945), pp. 305-12; J. M. Clark, "Toward a Concept of Workable Competition," *Am. Econ. Rev.*, June 1940, XXX, 247.

Which position was actually reached would depend on the number of firms that happened to be in the industry.

By varying our assumptions we have found several alternative sets of conditions of long-run equilibrium: (1) that in which the number of varieties (among those numbers capable of being produced at a cost equal to price) is maximized, quality height being adjusted to the level necessary to achieve this maximization; (2) that in which quality height (among those heights capable of being produced at a cost equal to price) is maximized, the number of varieties being whatever number makes possible this maximization; and (3) various intermediate positions, in which vertical quality is higher than in the first case though less than in the second, while the number of varieties is greater than

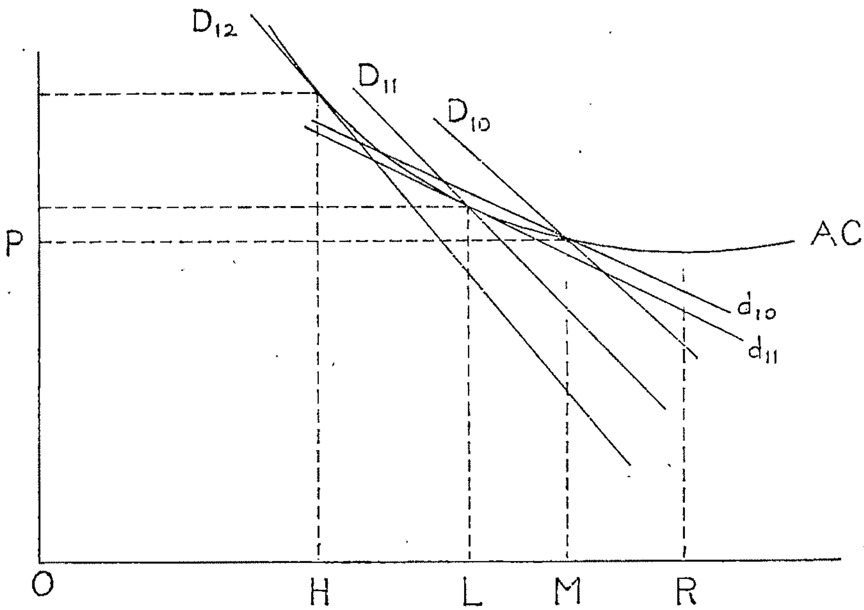

FIGURE 3

in the second case though less than in the first. We have located a *range* of equilibrium positions.

That there is a range rather than a single position is not due to the fact that competitive adjustments are forced to take the form of quality changes rather than price changes. The equivalent of each of these positions can be shown on a conventional diagram of a firm selling a differentiated product of fixed vertical quality in a monopolistically competitive market.

Equivalent to the case of concurrent quality changes is the case of

concurrent pricing, which, when employed by profit-maximizing firms, maximizes joint profits. Each firm adjusts its price on the basis of a demand curve which is $1/n$th the industry demand curve, n being the number of firms. In Figure 3 such a demand curve is shown as D_{10}. If firms have been producing for a market in which price has been fixed at OP and are now free to alter the price, they can gain supernormal profits by raising the price. But entry of new firms will shift the demand curve leftward. Equilibrium is attained at OH when the curve reaches the position D_{12} where it is tangent to the cost curve.

The equivalent of our second equilibrium position can also be shown. Its conditions correspond to the Chamberlinian assumptions. Each firm's demand curve (based on the expectation that prices of other varieties remain unchanged) is more elastic than the curve showing the volume of sales when all competitors' prices change too. Equilibrium is attained at OL when entry of new productive capacity pushes D_{10} leftward to the position D_{11}, where the firm's demand curve, which was d_{10} and is now d_{11}, becomes tangent to the cost curve.

The equivalent of our third equilibrium position, based on desire to maximize output, acceptance of average-cost pricing as a norm, and willingness to take temporary losses, is at OR.

These comparisons enable us to see how similar to price variability in its final effects is vertical quality variability.

VI. *Implications of the Analysis*

The writer is fully aware of the limited scope of the analysis just presented. The model studied illuminates only one small corner of the great arena of quality competition.

By restricting ourselves to a study of *equilibrium,* we have obtained a picture of competitive behavior with regard to quality variability which is highly artificial and seriously incomplete. This is unavoidable. A prerequisite of equilibrium is the attainment of perfect knowledge (or, alternatively, an unalterable state of knowledge). Equilibrium analysis therefore turns its back on the semi-ignorance, uncertainty, and exploratory character of real-life economic activity. The typical patterns of quality competition are in large part founded on disagreement as to the best means of satisfying wants, and reflect the continual experimentation that is so strikingly characteristic of economic behavior. Innovation is intelligible only when viewed in such a setting; it is inherently experimental, risky, a challenge to the current state of knowledge and currently prevailing attitudes. Equilibrium analysis, on the other hand, necessarily assumes that the newest ideas have become common property, and have been tested out long enough so that their

value is no longer in doubt. It therefore omits this important aspect of economic behavior, revealing only those aspects of quality competition that are connected with cost differences and the diversity of wants.

By further restricting the analysis to a study of *vertical* variability of quality, we have neglected the important area of horizontal variability, in which decisions regarding quality affect the range of choice open to buyers, and the degree to which products conform to buyers' needs and tastes and are suitable to the uses to which they are put.

Our analysis would also have been more comprehensive if it had not abstracted from certain frequently found conditions in the real world—for example, semi-ignorance, gullibility, and the bewildering complexity of choice when quality variability is multidimensional and information about quality and product performance is not readily available.

Nevertheless, the analysis has been of some use. It has made clear one thing which may be familiar enough to observant students of economic life but which customary methods of economic analysis do not show: namely, that vertical quality competition performs essentially the same functions that price competition performs. Whenever price is excessive relative to product—or, to put it the other way round, whenever product is deficient relative to price—it causes producers to revise their offers, making them more attractive. Thus, like price competition, it induces behavior which results in the elimination of excessive profits. Similarly, the firm's equilibrium position in a fixed-price market with vertical quality freely variable appears to be identical with the position reached in a fixed-quality market with price freely variable. When products are horizontally differentiated, and when firms seek to maximize profits, the firm's output falls short of that at which unit cost is minimized. It could also be shown that, when horizontal differentiation is lacking, output settles at the minimum-cost rate. Thus vertical quality competition, like an able understudy, steps into the breach when price competition ceases to function and brings about results usually associated only with price flexibility.

The analysis thus makes it clear that a uniform, unchanging price is not necessarily evidence of lack of competition. Absence of price variation may indicate merely that competition is restricted to the quality dimension. Only when quality is also uniform and rigid is competition lacking. Unless economic investigators are aware of the inverted "price" competition that can occur when vertical quality is variable, they may be led into serious error in their appraisal of the competitiveness of certain industries.

In industries characterized by quality flexibility, the term *price*

rigidity is inappropriate, since it has no economic significance. The term is surely misused when applied to situations in which the price of B on Tuesday is the same as the price of A on Monday; it can be meaningful only when both prices refer to the same product, and to a specified unit of specified quality. When the unit is fluctuating in size or quality, we are moored to a shifting anchor; price would have to fluctuate similarly in order to produce a situation comparable to that of a rigid-price, rigid-quality market.

All this suggests the need for a broader approach to the oligopoly question. Unless quality is uniform and invariant (and actual prices coincide with published prices) the price theorist's analysis of oligopoly is based on incomplete data. The extent to which the results associated with competition are realized in an oligopoly situation cannot be correctly assessed without taking into consideration conditions with respect to quality differentiation and variation. Model-building of the sort attempted in this paper may help to turn the attention of economists to factors in market situations whose importance has hitherto been underestimated.

"REALISM" IN POLICY ESPOUSAL

By Clarence Philbrook*

Economists in general have learned to live under the recurring charge that they are "unrealistic." The term may, of course, mean many things. Where the meaning applies to what they do strictly as "scientists," the barbs need not go deep. Against such slings and arrows there hangs ready a familiar armor—namely, the prestige of scientific method, made magically tough by having clothed also those heroes of the battle for knowledge, the natural scientists. Not always are economists content, however, to remain "scientists" describing relationships and eschewing reference to the desirability of things, or even to remain "engineers" suggesting devices to achieve ends laid before them entirely by others. They do step out of these rôles and give their society, or some sector of it, advice which commits the adviser to responsibility for value judgments.[1] They do "take positions"—act as advisers in a full sense. In this rôle too they are often faced with the charge of being "unrealistic."

Used in this connection the epithet becomes a different missile and will not be turned aside by the same armor. What range of meanings may possibly attach to the term need not for present purposes be explored. One particular connotation which it frequently carries will be singled out and attributed to the word. This meaning is, that the economist charged with "unrealism" has made recommendations requiring for their fulfillment changes in things which must, for the purpose at hand, be treated as unchangeable. It would be brash to deny that such a charge may often be true. A basic responsibility implied in it has, at any rate, a valid claim to attention: *of course* the economist, to give useful advice to society, must regard various things as in a significant sense beyond our power to alter. Failure to do this seems virtually a definition of idle dreaming. Wherever he has failed to be guided

* The author is associate professor of economics at the University of North Carolina. He expresses thanks for criticism and stimulating discussion to Mr. George M. Woodward, Major Robert L. Bunting, Dr. Edwin J. Stringham, and Professor Dudley J. Cowden.

[1] Throughout this paper the word "advice" and terms used synonomously are to be interpreted in the broadest possible sense—to include any recommendation, inside or outside the classroom, made without hypothetical purpose clauses more restrictive than the necessarily implied aim to achieve the desirable.

properly by this precept, the economist must indeed confess that he has sinned.

Yet there is a more cankerous sin which economists have all too often committed in order to escape indictment. So great has become the scramble to turn state's evidence, that one who suggests a solution not treating as "given" ("here to stay") any particular popular social practice is merely fortunate if no colleague misquotes him Carlyle's response to Margaret Fuller's decision to accept the reality of the universe: "Egad, you'd better!" The charge of "unrealism" is used with telling effect to discredit policy recommendations without adequate consideration. It probably affects in no small degree the determination of what types of work are respected and supported in universities. Science has rightly been said to aim at stability of belief by cultivating doubt; but the spirit behind the familiar charge, by restricting the range of questioning deemed worth while, limits the use of science for this fundamental purpose. In so doing that spirit, on the negative side, creates a presumption that the time of scholars is readily available for other activity, and, on the positive side, implies that worthy uses for time must be sought elsewhere. It therefore fosters a test of scholars which, at a moderate stage of development, asks whether their activity is "constructive" (Does it build, not tear down? Does it look forward, not backward?) and, at a now common extreme, asks whether their activity immediately and discernibly influences practical affairs. Of course the man least demonstrably ineffectual is he who advises others to do what he knows they will do without his advice. Indeed, the competition for reputation as "realists" works toward a condition in which students of society are loath to take a minority position. Society tends as a result to lose the benefit of that disinterested, fundamental, continuous criticism which, unless provided by persons made independent of practical affairs for that very purpose, is unlikely to be forthcoming. There has grown a widespread practice of cooperation with "things as they are," without explicit criticism of them, which is bound to have the effect of active approval regardless of whether such is intended. Thus, the spirit of "Egad, you'd better!" bids fair to render the field of political economy not merely useless but actually damaging to the social welfare.

However, I wish to invite contemplation and discussion; for the practical consequences hinging upon the treatment of this issue are enormous, and yet the matter seldom crosses the threshold into systematic consensus-seeking, but rather remains a little-explored source of recurring irritation and *ad hoc* dicta. I should like, therefore, to avoid resting upon the controversial conclusion stated above, and find a more neutral point of departure.

Perhaps this can be found along the following lines. In deciding what advice to give, one clearly must regard some conditions as given. On the other hand, the very fact that some one is to be advised to do something which presumably he might not otherwise do means that not everything in the situation is being treated as given. Evidently what is at issue is "correctness" in the selection of things to be so treated. If we can find literally no criteria, consensus on policy is indeed hard to come by. It must then be impossible to force the "unrealist" to regard the necessary things as fixed; and, on the other hand, his critic can always, by "realistically" accepting the universe of his choice, find sanctuary against the necessity of defending his own positive policies. Is it possible to say anything helpful toward consensus about what actually constitutes "realism," in some defensible sense, in the selection of proposals on policy? It may turn out so, if we explore a path through a series of intellectual positions, asking how far it may reasonably be supposed that plaintiff and defendant can walk together and where they might feel forced to part company. The method will be to start with a position which a "realist" surely will not think labels alterable any conditions which are not so, and progressively introduce elements which he might consider less "realistic," at each stage inquiring whether he really would be likely to reject the new element. Finally the question will be raised whether the "realist" can reasonably insist upon any principle which would enable him to use meaningfully the familiar charge. An effort will be made to maximize the ease with which any telling rebuttal that may be available against the argument of this paper can be made, so that if the conclusions reached here are wrong the fact may be made clear and many of us may mend our ways in keeping with a sound "realism."

The position most safely "realistic" would seem to be that which took *everything* in the situation as given, including both the physical universe and the attitudes of all persons. One who adopted it would presumably interest himself exclusively in the discovery of regularities and the forecasting of events. The fact that this view by no means corresponds to the scientific outlook in total does not assure that the two are never thought to be identical. Such identification probably accounts in no small measure for the high prestige of simply any "empirical" research as opposed to "arm-chair theorizing": almost any conceivable collection of figures will be regarded in important quarters as representing a certain hard-headed practicality, while any serious discussion of what is the real significance of the collection is considered either jealous carping or mere mental gymnastics by minds too lazy to do "constructive" work. Finding "what the facts are" is the great task

according to this view; for, if they were once discovered, we should then be in position to make forecasts.

This position has great appeal to men of scientific bent, and indeed to all of us. It is "obvious" to common sense that every effect must have a cause and that any state of mind must be an effect of preceding states of mind, body, and environment. To be sure, some embarrassment may arise in trying to find a function and purpose for the scientist himself; for, although the surrounding stimuli may cause him to emit sounds and cause us to call the sounds a forecast, he cannot in this view "influence" anything, and the notion of function, including that of purpose, is itself meaningless. Nevertheless, the mere fact that an analyst will typically use words which imply that his conclusions are yet to be determined by the effort of investigation or discussion does not prove the deterministic position false. Activity that is apparently purposeful may be viewed either as the result of a free will operating with its available means toward some goal, or alternatively, as the movement of a set of pre-established forces working toward equilibrium. In the determinist view the pseudofunction of the scientist is that of a cog in a machine. The tempting query why, if determinism is true, the scientist would struggle as he does, or society pay him to do so, is itself meaningless, for "would" no longer can connote volition and "struggle" has no meaning; he and society do not do, in any significant sense, what they think best—they simply do.

The well-known and fatal difficulty with the deterministic attitude that we must treat everything as given is that the truth of its opposite also is obvious and is inevitably dominant in our procedure. It is certainly impossible for the mind to act regularly as if it regarded itself as an epiphenomenon accompanying the burning out of a physicochemical reaction. Although nuclear physicists could not alter the fact of the fissionability of the atom, it is said that some of them believe they could (as well as should) have refused to discover the fact or, at least, to put it to its most famous use. No analyst will, where it counts, cling to a purely deterministic position. All will "play like" their "decisions" are decisions in the common-sense meaning of the word and capable of affecting reality.

Social analysts as advisers will, then, take at least one step away from regarding everything as given and still feel themselves to be "realists." The most modest step is exemplified where the analyst occupies an administrative post with some discretionary power. A man in that position would believe that the word "discretion" had some meaning—that the external situation could be influenced by a *decision,* such as, for example, to allow a certain wage rate to be raised. The step is modest in

that it leaves the scientist in the same instrumentalistic relation to the situation as he might bear to a group of chemical materials to be manipulated. Further, nearly all social analysts would take another step without at all losing a sense of "realism," in believing that they might actually influence the world by giving advice to crucially placed administrators or legislators—on occasion simply by making evident to them the truth of a cause-and-effect sequence or the validity of a value. Indeed, adding together these two steps, we have the basis for what appears to be regarded as the most valuable activity of analysts as social advisers, although a relatively high respectability seems to attach also to the act of advising organized pressure groups.

The range of possible change, and of influence of the social adviser, is relatively narrow if channels of influence are restricted to those just mentioned. For most important changes (usually legal) require a change of attitudes on the part of a large number of persons. This need not appear true, to be sure, to one willing to take a purely instrumentalistic view. In that outlook, the range of action would be considerably broader, since it would be possible to advise holders of power to use their power "for the good of the people" with small regard for what the people thought they wanted. Indeed, much recent history of government might be accounted for in terms of a general belief that "realism" is violated by those who hope social advisers may have influence otherwise than directly. This instrumentalistic position need not disavow the possibility of change in mass attitudes: a benevolent government may "educate" the people to agreement with its measures. This is a clear-cut, possible intellectual outlook; but if such neo-Machiavellianism is to be espoused, the social scientists adopting it should make as clear as they can that they have given up hope of that consensus-created, not merely consensus-creating, government which is usually called democracy. Those who believe that consensus should precede political action must, it is merely tautological to say, believe the archetype of their "action" as advisers to consist of effort to help others discover correct attitudes; so we may suppose that, in considering attitudes to be among the alterable conditions, we still have the company of "realists" whose ultimate values include a rôle for democracy.

Since important changes in society do require alterations in the attitudes of many persons, social analysts, in order to form opinions on what changes would be worth while if they could be brought about, must often consider at great length what processes would go forward under assumed conditions which are often at variance with the facts. Strangely, by carrying on such considerations carefully rather than carelessly, men call down upon their heads some of the most scornful

charges: "unrealistic," "too theoretical," "purist," and the like. Yet it is difficult to see what could be more "unrealistic" than saying that a change would be worth while (unless mere change for its own sake is the sole issue) without first methodically considering what results might reasonably be expected. So surely it may be assumed that the school of "realism" would accept the study of "models," or "theories," as indispensable.

It is in deciding what alterations of attitude to attempt, that the point arises which presumably most persons stressing "realism" have in mind. Should we not, they might ask, distinguish among conceivable changes according to whether we stand some reasonable chance of actually effecting the necessary shift of attitude? Why waste effort by making suggestions which we cannot hope will be accepted? These queries appear to have much justice. The idea obviously is that one ought to list the actions open to him and attach to each a weight determined by the probability that it would in fact bring about the attitude change intended.

If we described a "pure realist" position as calling for decision by simply selecting the advice with the highest "probability" weight, we ought to be able to treat it as only a straw man. To be sure, the mere fact that most "realists" would reject an approach so stated does not mean it really differs from what they have effectively in mind; a major part of the thesis of this paper is that numerous economists are in effect espousing positions which, if stated clearly, would be repudiated by them. Nevertheless, one fatal criticism of any such bald "probability" approach must surely be treated as noncontroversial. No one would explicitly maintain that a high relative probability of having *some* effect should give priority to an act completely without regard to the relative desirability of the outcome it would tend to have. It seems reasonable to suppose, therefore, that the "realist" would accept as a part of "realism" the necessity of consulting end values as determinants of advice.

It becomes important, then, to recall what is required in due allowance for this element of "realism"; for, although few would deny its claims in the abstract, many become quite impatient when called upon in specific cases to give full weight to it. (Who having experienced the earlier years of the New Deal can forget how frequently the conclusive defense of almost any policy was that the government was *doing something*!)

Evidently the adviser, having arrayed the lines of advice he might give on a particular issue, must assign a weight to each according to the desirability of the change it would tend to promote. A change can be desirable otherwise than for the sake of novelty only as it furthers some

end. But since there are conflicts of ends, an action may further one end and lessen the realization of another, and the net significance cannot be known without first evaluating the various ends (or degrees of realization of them). Relative evaluation requires a common measure, hence can be accomplished only if the "ends" are but intermediate, serving in turn as means to, and deriving their value from, a more general end (which itself is merely one of a number of ends all serving as means to a yet more nearly ultimate goal.) Assigning the correct desirability weight to a change means judging its net influence upon the realization of some end sufficiently general ("high") to include all the intermediate ends touched by the change; and this judgment involves tracing the effects of the change upon each intermediate end and evaluating those effects in each case by reference to the inclusive end. Thus, literally full justification of the whole set of value weights one attaches to a set of policy suggestions would require laying bare the relations between the proposed changes and some all-subsuming, ultimate end of social organization. Only in this way could the mutual consistency of all the various means and subsidiary ends which constitute a total program for society be established.

In discussion aimed at consensus, the problem is one of showing a disputed policy to be a means to some intermediate end and then inquiring, of parties to the discussion, whether this "end" is in their view necessary as a means to what they regard as some more fundamental goal. If not, agreement is not logically called for. The proponent must then try to show that the disputed "end" is a means to something he himself regards as a more fundamental end, and if successful repeat the query. It is for present purposes unnecessary to dwell upon the complexities hidden under the light reference to showing a disputed end to be a means; what is needed is merely a suggestion of the extensiveness of the obligation taken on by acceptance of the necessity of value weights and consensus. If consensus is to be soundly reached, a process of the sort indicated must go forward until the derivation of importance is traced back to some end the authenticity of which is accepted by the parties to the discussion. Fortunately, it is usually not necessary to go far toward ultimates; but the ideal student of policy, far from refusing to talk about the sheer desirability of a proposal opposed to his own, would stand ready and eager to reduce the two, no matter how different, to commensurability in the manner suggested.

There is good reason to be appalled by the difficulty of the task cited, especially in a world become self-conscious and discordant about its values. It is of no avail, however, to assail as "purists," "absolutists," or "unrealists" those who call attention to the task. The only alternative

to readiness to defend a position in the sense indicated is to grant that at least some of one's means and intermediate ends have not been tested for mutual consistency, and that one's policy proposals have therefore no more authority than some diametrically opposite set. These considerations surely place a demand upon an economist giving advice on social policy that he shall have thought his way through, so far as the state of knowledge makes possible, to an internally consistent model of economic organization on which he bases his advice. The gravity of the potential effect of error in policy, and the immensity of the scope for growth and ripening of intellect toward power to grapple with the problems involved in discerning good policy, render merely ludicrous the widespread impatience toward "arm-chair theorizing," which, unless the integrity of the men involved is in question, must be regarded as an arduous process of critical contemplation and integration aimed at the development of wisdom.

Of course nothing in the foregoing discussion denies the notion that the end must be dealt with in the light of the availability of means. Neither is it affirmed that "the end justifies the means" in the sense that there is any end for the furtherance of which no device is too bad; but the ultimate end itself must contain criteria of acceptability of means, so that the means, if justified, are indeed justified by the end. Even though strong doses of starvation might have shortened immensely the employment depression of the 'thirties, the ends of the society justified the relief of distress. These things are probably all that need saying about the perennial argument over the short-run versus the long-run view in the selection of policy; yet one's faith that the full import of attributing value weights is noncontroversial is bound to be shaken by memory of how often any manifestation of the long-run view is answered with some form of the completely irrelevant "realistic" proposition, "In the long run we are all dead." Although this reaction has done much damage to the search for sound policy, by limiting the consideration of ends, it may nevertheless reasonably be interpreted as something other than repudiation (in the abstract) of thinking in terms of ends and means. Indeed, it is probably as a rule a confused, distorted, and misapplied criticism, not of means-ends thinking, but of presumed failure to apply fully such a calculus. More often than not, the thought reflected is simply a generalization of the example given above: the idea that the time dimension must be allowed for—that radical change takes time and meanwhile we must make the best of the situation, perhaps by means which hamper realization of some accepted goal. To be sure, a proposal involving thought of the long run might often be criticized because it seemed to violate the true

"probability" approach, which we shall in a moment try to state. But, it may be taken for granted, relatively few "realists" would question that in such an approach value considerations must have a place.

It seems possible now to sum up the most likely meaning of a "probability" approach—a position which must be the one that would be held by any who, in the light of considerable discussion, still were willing to make use of the charge, "unrealistic." Although in some cases only under pressure, they surely would accept these propositions: that many elements in a social situation are capable of change, including the attitudes which determine policy; that actions of individuals in their rôle of "social advisers" could have some influence on those attitudes; and that the advice to be given by them cannot be chosen without the aid of weights attached to different lines of advice according to the relative desirability of the change which these respectively would tend to further. They would insist, however, that a choice can be made only after superimposing another weight on each line of advice according to the probability of its taking effect if offered. Men called "unrealistic" are those who disregard this principle and presumably those who assign probability weights incorrectly.

There is a considerable appearance of reason about this method of thought. Still, it requires the most careful inspection.

It is important not to slight the fact that two lines of advice such as typically give rise to controversy over "realism" are not necessarily so related as to make "probability" considerations relevant at all. A believer in states' rights, for example, presumably may make clear his belief while yet offering good counsel on how best to operate a program which disregards such a conception. The relation required if "probability" is to have any place is that the two lines of advice be truly alternative—that is, mutually exclusive.

Two possible causes of mutual exclusiveness are suggested. First, sheer limitation on time, energy, and intellect requires specialization; and some decision must be made as to the field in which to develop special competence. May one not make an ample contribution by advising the Federal Reserve authorities how best to use their powers, without questioning whether the present banking system is the best conceivable? Actually, specialization raises no problem. The question is whether, not having studied the possibilities of alternative systems, the specialist causes or allows it to be supposed that his activities constitute support of this system against alternatives, or whether, having decided another system would be better, he conceals the fact. If one applies "probability" thinking and recommends that approach for others, it must be from sources other than specialization that he derives the implied mutual exclusiveness of different pieces of advice.

The second cause of mutual exclusiveness which the "realist" presumably has in mind is that the very act of approving a different general course may destroy power to guide action along the best path in an established, although less desirable, direction. There is no denying that suggestions from one listed among the faithful with respect to a program are, as "self-criticism," more likely to wield influence than is advice from "outsiders." Thus we can identify conceptually a type of case in which the lines of advice are alternative in a sense sufficient to justify at least entertaining the question of whether it is desirable to be guided by "probability."

It goes without saying, that the mere identification of such a class of cases gives no license to beg the question of whether any particular case belongs to the class. If indeed "probabilities" are sometimes a proper guide, the epithet "unrealistic" can at best be justified only upon an explicit showing that giving one of the lines of advice does preclude the usefulness of giving the other. But even for use in cases where "probability" is formally relevant the "probability" approach is open to grave doubt on a number of scores.

In the first place, what is the criterion for the relative weighting of a "degree of probability" and a "degree of desirability"? There is always the devastating possibility that the total weight of an action in keeping with a completely evil outcome might be greater than that of one tending to further a desirable end. Suppose that in Germany under Hitler it appeared that one hundred thousand Jews would probably be bayoneted to death. Should I, if a German, have suggested merely a less brutal execution by gas—thus quite possibly doing *some* good—or should I have cried out against the whole idea, quite probably having no discernible influence? And, if I decided on the former, should I have claimed credit as a "realist" and decried as "unrealistic" any who advised the society to let the Jews live?

In the second place, the problem of actually assigning "probabilities" must be faced—some aspects of which are relegated to our third and fourth points. At present we may consider the matter from a relatively uncomplicated point of view. The task of assignment involves knowing attitudes, including in some sense their "strength," and the force of the impact of each suggestion under consideration as tending to change them. Diffidence about analyzing matters of "attitude" would become us, for there are indications that merely agreeing upon a scientific content for the term might keep sociologists busy for some time. However, it appears that an attitude rests upon at least these underlying factors: a value system, the "brute" elements provided by the senses, and theories relating these elements. Thus, basic to assigning "probabilities" would be a knowledge, with respect to each person affecting the adop-

tion of a policy, of how these factors combine in him to form attitudes, including what is the "marginal influence" of changes in the respective factors. Given such information, successful forecasting would require discerning also exactly what persons the advice would reach and in what form and, for each person reached, just what changes would occur in each of his attitude-making factors. (Since forecasts are, for the purposes in question, to run in terms of probability distributions, the knowledge required—whatever its nature—would be more rather than less complex than these statements suggest.)

In the case of an official economic adviser to one or a few immediate determiners of policy, presumably sufficient knowledge for a forecast might be possessed—although it would be naïve to take for granted that the enigma which man presents to man regularly yields to the degree of intimacy involved in such a relationship. However, to assay how appropriately the cited requirements might in general give pause to a forecaster, it would be well to recall what must be meant by "lines of action" open to economists as social advisers. These vary greatly as to immediacy of impact upon policy, ranging from the report of an official adviser, through systematic promotion (honest propaganda), down to a mere planting of seeds of thought whether in the classroom or in casual conversation. Evidently the overwhelming majority of "actions" exercise their effects quite indirectly. What is the "probability" that a policy-influencing marginal change in attitudes will result from planting an idea, or the means of arriving at good ideas, in the classroom or in an address or in social intercourse? With what degree of immediacy, both in point of time and in point of the number of intermediate impacts? A mere showing of difficulty would not invalidate the conception of a "probability" approach. But it would scarcely be extreme to suspect that estimates of "probability" would in the case of most expressions of espousal have a probable error so large as to render them "statistically" insignificant.

The knowledge stipulated as necessary was not characterized as sufficient for the appraisal of "probabilities." Indeed, contemplation suggests some mystery about the very nature of such a process in the kind of universe in question. These facts suggest a problem which for emphasis we may single out as our third point: a fundamental difficulty in the very notion of "probability" as a property of the force of a piece of advice. Unless the intent is simply to lead others to act under false impression of the results to be expected, advice consists of making evident the soundness of an idea and relying upon the resulting recognition of that soundness to cause action based upon it. The force at work changing attitudes is, then, "idea force." "Probability" implies a mechanical relation, some kind of quantitative continuity. But correct conclusions

cannot flow from treating "idea force" as if the law of conservation of energy applied to it; for, however an idea may get into a mind, it is capable of dying there or of gathering immense force. Moreover, a number of minds can be seeded with one expression of the idea. Potentially, then, the force may grow at an astronomical rate. All the determinants of whether it dies or gathers strength in a particular mind, we simply do not know. We do know, however, that that which is believed to be true has an appeal to the mind believing it, over and above the attraction it may have on other grounds: truth has a positive appeal in its own right. Although other appeals may swamp this one, there is no limit to the possibilities of its breaking through and causing action. The degree of apparent influence of the person holding an idea is, therefore, no measure of the potential effect of his giving utterance to it. If there is one belief fundamental to, and universal in, our culture, it is this notion that truth as such has power. Such justification as may exist for the hope of a better world lies here and here only. In the face of these considerations it seems doubtful, not merely whether we can effectively measure "probabilities" for different "actions" upon attitudes, but indeed whether any real meaning attaches to the conception.

In the fourth place, to guide oneself by a "probability" calculus is one thing, but to say then that all persons should do likewise is to fall little if at all short of nonsense. There might be some sort of rationality to urging that others espouse according to value weights only, so as to leave one or a few free to add the "probability" factor. The latter procedure implies estimating the current division of the forces of espousal and deciding whether one's own influence would suffice to change an inferior force into a superior. Evidently, then, much of the force exercised by others must have been somehow committed. If all, however, follow the "probability" principle, no one can commit himself until many others (nearly all?) have committed themselves. Thus, for keeping public affairs relatively free from the influence of the disinterested, the "probability" principle would be a reasonably effective device.

Since it would seem harsh to attribute to the "realist" a meaning so patently foolish, an attempt at a different interpretation may be appropriate. Although the inference does not appear obviously logical, could the actual meaning involve a process in which the many individual advisers, each with the "probability" factor in mind, somehow simultaneously determine their respective positions? If so, to be sure, the implications are still not attractive. Major economic policy, in so far as it is influenced at all by economists, apparently ought to be the product of infinite involutions of guesses by each about what others are guessing about what he is guessing about what they will advocate! However, for example, having advocated farm-price supports on grounds of their

"probability," it appears that one may take a fearless stand in favor of ninety per cent of parity as opposed to ninety-five per cent—unless, indeed, the probabilities are too much against that. It is a depressing picture of the rôle of representatives of that higher learning upon which much of the hope of social improvement has sometimes been supposed to depend.

In view of the preceding point, a fifth one is evident: the "probability" approach rests upon an ethical atomism which might reasonably be supposed long ago to have been barred by a well-established principle of ethics, that a precept is unacceptable for one man unless it would have an acceptable outcome when followed by all. In the face of this principle, how can the degree of immediate influence of a scholar upon practical affairs be deemed a matter of greater concern than the desirability of the direction of such influence as he does wield?

A sixth and major indictment of the "probability" approach, although contained in much of the preceding discussion, should be made explicit. Fundamental to such a procedure is the fact that, while believing one course to be the best, I say or allow it to be thought that I believe a different one to be the best. That is to say, the approach explicitly calls for the active or passive concealment of truth. It should scarcely be necessary to argue against an idea which so patently strikes at the foundations of scientific integrity.

If the thoughts assembled here are sound, men will best serve the cause of social welfare if they refrain both from disposing of opponents as "unrealistic," in our defined sense, and from bowing to fear of that charge in selecting their own positions on policy. Degrees of "probability" are incommensurable with degrees of value, and ethical considerations do not permit the former to outweigh the latter. The assignment of "probabilities," even with a highly oversimplified conception of their meaning, would in the great majority of cases be so difficult as to become absurd. The nature of "idea force," moreover, makes it doubtful whether any real meaning attaches to the very notion of "probabilities of success" of different lines of advice and whether, therefore, there can be any such weights to superimpose upon value weights. In any case, to call the "probability" approach proper for all who take a position on policy would be to advocate a practice which would remove any rational basis which "probability" estimates might be imagined to have, by reducing all policy position-taking to a logically impossible universal mutual anticipation ending only in universal support of the *status quo* (in so far as change depends on deliberate human planning), and which would of course divorce policy selection from reference to value. Finally, the required concealment of truth is intolerable to the most

fundamental conception of the scholar's reason for being. The "probability" approach must surely be rejected, to say nothing of its being considered prerequisite to respectability. Only one type of serious defense of a policy is open to an economist or anyone else: he must maintain that the policy is good. True "realism" is the same thing men have always meant by wisdom: to decide the immediate in the light of the ultimate. The economist must follow this ideal as best he can—in humility and in readiness to compare notions both of technical relations and of ultimate values.

"FULL EMPLOYMENT" 1955–1960—A FEASIBILITY TEST

By ROBERT STANLEY WEINBERG*

It is my purpose in this paper to outine a set of supply and demand requirements for "full-employment" in the period 1955 through 1960. In Part I a simple model defining "full-employment" in terms of total output, Gross National Product, is developed. Part II considers recent past trends and empirically projects a set of annual "full-employment" GNP levels consistent with the model outlined in Part I. Part III contrasts the total supply estimates derived in Part II with the projected demands of the consumer, business, government, and foreign sectors of the economy to test the feasibility of "full employment" under various assumptions. Finally, Part IV summarizes the implications and feasibility of "full employment" through the 1955–1960 period

I. *"Full Employment," a Simple Model*

This oversimplified model considers the interrelationships between seven broad variables, the population (P), the labor force (L), employment (E), unemployment (U), the length of the average work week in hours (H), productivity, the output per man-hour labor input (T), and total demand (GNP).

The interrelationship between these variables can be defined with the following set of equations:

$$L = f(P) \qquad \text{I:I}$$

The labor force is a function of the population, that is, the size of the labor force is related to the size of the population.

$$L - E = U \qquad \text{I:II}$$

This equation is merely the definition of unemployment. Unemployment is equal to the difference between the labor force and employment.

$$\frac{GNP}{(T)(H)} = E \qquad \text{I:III}$$

* The author is a consulting economist and econometrician. The research on which this article is based was conducted while the author was on active duty as an officer in the United States Air Force. The views expressed in this article represent those of the author and do not in any way represent official United States government, Department of Defense, or Department of Defense Agency, opinions or planning.

Equation I:III defines the level of employment as the quotient of GNP divided by the product of productivity, output per man hour, times the average hours worked.

At this point we may now introduce an eighth variable, minimum frictional unemployment (U_f), or that level of unemployment that will be acceptable at a "full-employment" level. By definition, "full employment" will exist when $U = U_f$. The exact level of demand required to attain a level of "full employment" is that level of demand that yields the identity

$$U = U_f \qquad \text{I:IV}$$

To arrive at that level of demand required to attain exact "full-employment" equations I:II through I:IV can be solved simultaneously to yield equation I:V,

$$\overline{GNP} = [L - U_f](T)(H) \qquad \text{I:V}$$

where $\overline{GNP}$ is equal to the level of demand required to sustain exact "full employment."

If U_f is taken as either an absolute (*i.e.*, millions of workers) or a relative (*i.e.*, a percentage of the labor force) constant, equation I:IV determines $\overline{GNP}$ in terms of three variables, L, T, and H.

The expression $L-U_f$ can be replaced by $\overline{E}$ which represents the level of employment at a "full-employment" level. Similarly the product of T times H can be replaced by a single term Z, where Z represents the output of one worker, *i.e.*, the workers' hourly rate of output times the number of hours worked.

Equation I:V is now reduced to simply:

$$\overline{GNP} = (\overline{E})(Z) \qquad \text{I:VI}$$

For the purposes of future discussion we will consider projected levels of $\overline{E}$ as being primarily the resultant of a set of unique combinations of various demographic, sociological, and economic factors, Z will be considered as being primarily the resultant of a set of unique combinations of various technological and economic factors.

The supply and demand estimates developed below should not be considered as forecasts, but rather as long-term trend projections. These projections assume a continuation of the basic trends indicated below. It should be remembered that in reality, at best, we would expect the "actual" levels of supply and demand to fluctuate about the trend values shown below.

II. *Some Empirical Projections of "Full-Employment" Levels*

Part I presented a generalized oversimplified model defining full employment in terms of "full-employment" levels of Gross National

Product. In this section a set of "full-employment" GNP levels will be projected consistent with the basic conditions outlined in the derivation of equation I:VI above.

We will begin our analysis with a projection of the size and occupational distribution of the labor force for the six-year period 1955–1960 as shown in Table I.

TABLE I.—THE LABOR FORCE EMPLOYMENT AND UNEMPLOYMENT, 1955–1960

(millions of workers)

	1955	1956	1957	1958	1959	1960
Total Labor Force	69.1	70.0	70.8	71.7	72.6	73.5
Armed Forces	3.0	2.5	2.2	2.0	1.7	1.7
Civilian Labor Force	66.1	67.5	68.6	69.7	70.9	71.8
Total Employment	64.5	65.8	66.9	67.9	69.1	70.0
Nonagricultural	52.0	53.5	54.8	55.8	57.2	58.0
Agricultural	6.5	6.4	6.3	6.2	6.1	6.1
Government	6.0	5.9	5.8	6.0	5.8	5.9
Federal	1.9	1.7	1.5	1.5	1.2	1.2
National Defense	.9	.75	.56	.55	.35	.35
Non-National Defense	.96	.95	.94	.92	.9	.9
State and Local	4.1	4.2	4.3	4.5	4.6	4.7
School	1.7	1.8	1.9	2.0	2.1	2.2
Nonschool	2.4	2.4	2.4	2.5	2.5	2.5
Unemployment	1.6	1.7	1.7	1.7	1.8	1.8

Table I is constructed on seven basic assumptions. It will be noted the part played by the federal government "as an employer," *i.e.*, the size of the armed forces and the size of federal government employment are minimized. This assumption implies a termination of the "cold war" by not later than 1954 with a transformation to a complete peace-time economy beginning about 1955 (the implications of alternate assumptions will be discussed in greater detail below). The basic assumptions underlying Table I are as follows:

1. The total labor force estimates are based on a Bureau of the Census projection.[1]

2. The size of the armed forces is based on the assumption that a peak of some 3.5 to 4.0 millions will be reached in 1954 to be followed by a period of gradual demobilization from 1955 through 1959 reducing the

[1] U. S. Bureau of the Census, *Current Population Reports—Labor Force*, Ser. P-50, No. 42, "A Projected Growth of the Labor Force in the United States under Conditions of High Employment: 1950–1975," Dec. 10, 1952, p. 7; U. S. Bureau of the Census, *Current Population Reports—Population Estimates*, Ser. P-25, No. 58, "Provisional Revision of the Total Population of the United States: July 1, 1953 to 1960," April 17, 1952, p. 1 (see also P-25, No. 43, Aug. 10, 1950, "Illustrative Projections of the Population of the United States 1950 to 1960," p. 11).

total armed forces to a new peace-time high of 1.75 millions.

3. The total civilian labor force is the total labor force minus the armed forces.

4. Total civilian employment is taken as .975 times the total civilian labor force. We will assume a minimum acceptable level of frictional unemployment (U_f) of 2.5 per cent. (This assumption will be discussed more fully below).

5. The projected declines in agricultural employment are based on an extrapolation of the 1900–1950 trend, adjusted to weight the more recent post-World War II experience more heavily.

6. Government employment is estimated in two components:

(a) Federal government civilian employment is based on an annual cross-section analysis of 1945 through 1949 data taken from Fabricant's study.[2] Federal government civilian employment is projected in two components: National defense and non-national defense employment. State and local government is also projected as the sum of two components, nonschool and school employment. Federal national defense activity employment is assumed to be a function of the size of the armed forces assuming the following rate of civilian employees per one thousand men in the armed forces: 1955–1956, 300 civilian employees; 1957–1958, 250 civilian employees; 1959–1960, 175 civilian employees. (In 1947–1949 there were about 348 civilian employees for each 1000 men in the armed forces, in 1937–1939 this ratio was 522 per 1000, and in 1927–1929, 348 per 1000.) Nonnational defense activity civilian employment in 1955 is assumed to be about 10 per cent below the 1947–1949 average; gradual declines are projected thereafter. These declines are assumed to be the product of two factors, the demobilization of the armed forces and related defense efforts and the streamlining of the other nondefense sectors (agencies) of government.

(b) State and local government employment represents a projection of three-decade 1920–1950 trend with an upward adjustment to take into account the levels and composition of the population,[3] particularly the sharp increases in the projected population of primary and secondary school age. Total state and local government employment in 1960 is projected at about 1.4 million above the 1947–1949 average. Nonschool employment is projected at about .5 million above the 1947–1949 average, school employment is projected about .9 million above the 1947–1949 average.

7. Those employed workers who are neither employed in agriculture

[2] Solomon Fabricant, *The Trend of Government Activity in the United States Since 1900* (New York, 1952), Tables B-5 (p. 180), B-6 (p. 182), B-7 (p. 186), B-13 (p. 196).

[3] See footnote 1.

or in government are assumed to be employed in nonagricultural industries.

Equation I:VI above expressed Gross National Product as the product of the number of workers times the annual output per worker. Once we establish the size and distribution of the labor force we merely require an estimate of the workers' annual output to develop our GNP projections.

We will project "full-employment" levels of Gross National Product ($\overline{GNP}$) as the sum of three components: (1) private nonagricultural GNP (GNP_n); (2) private agricultural GNP (GNP_a); (3) gross government product (GGP); where

$$\overline{GNP} = \overline{GNP_n} + \overline{GNP_a} + \overline{GGP} \qquad \text{(II:I)}$$

and:

$\overline{GNP_n}$, $\overline{GNP_a}$ and $\overline{GGP}$ = that level of product required to maintain that level of employment indicated in Table I.

To arrive at an estimate of the annual output per worker for the private sectors of the economy we require a projection of the workers' productivity and a projection of the average hours worked. The output of the government sectors is, by definition, the compensation of general government employees.

Two productivity projections have been developed, one for the agricultural sector, and one for the nonagricultural sector. Both of these indices are expressed in terms of 1951 constant dollar Gross Private Product per man-hour labor input. They were developed in the following manner. A set of annual estimates for the 1946 through 1951 period were developed based on the employment and hours data from the Bureau of the Census P-50 series and the Gross Private Product and supplemental employment data from the 1951 National Income Supplement of the *Survey of Current Business.* These estimates were then compared with those developed by a more careful cross-section analysis for three years 1949 through 1951 to yield a 1950 "adjusted trend value" for Gross Private Farm Product and Gross Private Nonfarm Product per man-hour labor input (see Table II). (The adjusted trend value is an estimate of the 1950 output per man hour adjusted to take into account an estimate of those changes, which reflect only short-term conditions.)

Gross Private Farm Product per man-hour labor input was then projected through 1960 based on an average of 1950–1960 decade, annual rate of growth of about 2.4 per cent. Gross Private Nonfarm Product per man-hour labor input was projected through 1960 assuming a 2.5 per cent average annual rate of growth.

Recent studies[4] have indicated that Gross Private Farm Product per man-hour labor input has increased at an average annual rate of 1.2 per cent through the four-decade 1909–1941 period. During this same period Gross Private Nonfarm Product per man-hour labor input has

TABLE II.—PROJECTED OUTPUT PER MAN-HOUR, AVERAGE WEEKLY HOURS, AND AVERAGE ANNUAL OUTPUT PER WORKER

	1950[a]	1955	1956	1957	1958	1959	1960
Projected Output per Man-Hour Labor Input							
Gross Private Nonfarm (1951 dollars)	2.67	3.02	3.10	3.17	3.25	3.33	3.42
Gross Private Farm (1951 dollars)	1.39	1.56	1.59	1.63	1.67	1.70	1.74
Projected Average Weekly Hours							
Private Nonagricultural		38.9	38.7	38.5	38.3	38.1	37.9
Private Agricultural		47.5	47.5	47.0	47.0	46.5	46.5
Average Annual Output per Worker							
Nonagricultural (1951 dollars)[b]		6109	6237	6346	6474	6597	6741
Agricultural (1951 dollars)[c]		3853	3927	3994	4081	4111	4207
Government—Federal							
Armed Forces (1951 dollars)[d]		3300	3300	3300	3300	3300	3300
Civilian Government (1951 dollars)[d]		4200	4200	4200	4200	4200	4200
Government—State and Local							
School (1951 dollars)[d]		3500	3500	3500	3500	3500	3500
Nonschool (1951 dollars)[d]		3200	3200	3200	3200	3200	3200

[a] Adjusted trend value.

[b] Average weekly hours (private nonagricultural) times 52 times output per man-hour (gross private nonfarm).

[c] Average weekly hours (private agricultural) times 52 times output per man-hour (gross private farm).

[d] Annual output of government employees is taken as equal to their annual wages and salaries (plus supplements).

increased at an average annual rate of about 1.9 per cent. In the present paper we expect farm productivity to increase at about twice the four-decade pre-World War II rate. This increased rate is expected to be the product of many new technological factors (*i.e.*, the development of new and more efficient farm machinery, increased mechanization, new chemical fertilizers, etc.) and general improvements in farming techniques.

The projected annual increase in nonfarm productivity exceeds the prewar rate through 1960. This increase assumes a continuation of the recent high levels of producers' expenditures for new plant and equipment and a continual improvement in the efficiency of this equipment.

[4] John W. Kendrick, *National Productivity and Its Long-Term Projection*, an unpublished paper presented before the May 1951 National Bureau of Economic Research Conference on Research in Income and Wealth. (See also, George G. Hagedon, *Productivity Gauge of Economic Performance*, National Association of Manufacturers, Econ. Pol. Div. Ser., No. 53, Sept. 1952 [New York, 1952].)

An analysis of preliminary data indicates an average rate of increase in nonfarm productivity of about 3.5 per cent in the postwar 1947–1951 period. While a long-term continuation of this high short-term rate of growth is questionable a continuation of a high-level investment program coupled with the gradual secular shift of workers to the higher productivity industries should assure an above average rate of increase at least through the 1950–1960 decade.

In 1951 agricultural workers averaged a 47.8 hour work week as compared to a 39.6 hour average work for nonagricultural workers.[5] Projected annual average weekly hours through 1960 are given in Table II.

From the projected figures for output per man-hour and for average weekly hours we may develop a set of average annual output per worker estimates by simple multiplication (see Table II).

The annual output of government employees is taken as equal to their annual wages and salaries (plus supplements). Our projections of average annual output per government worker assume a slight improvement in the "average rank" of members of the armed forces and the "average grade" of civilian government employees; that is, we assume that the ratio of "lower rank/grade" employees to "higher rank/grade" employees will decrease. Because of the difficulties involved in projecting changes in constant dollar government product, *i.e.*, shifts in the internal composition (the grade and rank structure) a constant average value is assumed throughout the 1955–1960 period.

We have now developed a set of average annual output estimates for each of the classes of workers in Table I. With the data given in Tables I and II we may now develop a set of "full-employment" estimates of Gross National Product through a simple process of multiplication and summation (see Table III).

The figures for Total Gross National Product in Table III show that level of total demand required to sustain a level of "full employment" consistent with the assumptions noted in Part II. In 1950 Gross National Product (in 1951 constant dollars) stood at 303.3 billion dollars. The next to the last line of Table III shows "full-employment" GNP relative to 1950 = 100.

"Full employment" through the 1955–1960 period would require an average annual rate of growth in aggregate demand of about 3.9 per cent through the 1950–1960 decade. To attain the 374.3 billion dollar level in 1955 would require an average annual rate of growth of about

[5] U. S. Bureau of the Census, *Current Population Reports—Labor Force*, Ser. P-50, No. 40, "Annual Report on the Labor Force 1951," May 19, 1952, Table 10 (p. 24) adjusted for workers "with a job but not at work" Table 2 (p. 16).

TABLE III.—"FULL-EMPLOYMENT" LEVELS OF GROSS NATIONAL PRODUCT

	1955	1956	1957	1958	1959	1960
Nonagriculture—$\overline{GNP}_n$ (1951 billion dollars)[a]	317.7	333.7	347.8	361.2	377.3	391.0
Agriculture—$\overline{GNP}_a$ (1951 billion dollars)[a]	25.0	25.1	25.1	25.3	25.1	25.7
Government—$\overline{GGP}$ (1951 billion dollars)	31.6	29.7	28.3	27.8	26.3	26.7
Federal (1951 billion dollars)	17.7	15.4	13.7	12.8	11.0	11.0
Armed Forces (1951 million dollars)[b]	9900	8250	7425	6600	5775	5775
Civilian Government (1951 million dollars)[b]	7812	7140	6300	6174	5250	5250
State and Local (1951 billion dollars)	13.9	14.3	14.6	15.0	15.3	16.7
School (1951 million dollars)[b]	5950	6300	6650	7000	7350	7700
Nonschool (1951 million dollars)[b]	7680	7680	7680	8000	8000	8000
Total Gross National Product—$\overline{GNP}$ (1951 billion dollars)	374.3	388.5	401.2	414.3	428.7	443.4
$\overline{GNP}$ Relative to 1950=100	123.4	128.1	132.3	136.6	141.3	146.2
Annual Increase (per cent)		3.81	3.28	3.25	3.44	3.47

[a] Average annual output per worker (1951 dollars), taken from Table II, times number of workers employed (millions of workers), taken from Table I.

[b] Average annual earnings per worker (1951 dollars), taken from Table II, times number of workers employed (thousands of workers), taken from Table I.

4.3 per cent between 1950 and 1955. The 443.4 billion level stipulated for 1960 would require slightly less than a 3.5 per cent annual rate of growth during the second half of the decade. Table IV compares these required rates of growth with some selected historical periods.

TABLE IV.—ANNUAL RATES OF GROWTH CONSTANT DOLLAR GROSS NATIONAL PRODUCT[a]

(per cent)

1910–1950	3.0	1946–1950	2.8
1929–1950	2.8	1950–1960	3.9
1939–1950	4.9	1950–1955	4.3
1940–1950	4.5[b]	1955–1960	3.5

[a] All rates are approximate. The 1910–1950 rates are based on the slope of a fitted trend line. The other rates are merely based on the two terminal years only.

[b] If the growth rate is computed based on the 1939, 1940, 1941 and the 1949, 1950, 1951 means, the rate of growth is slightly less, about 4.3 per cent.

Table V compares the projected increases in Gross National Product with the Bureau of the Census revised medium series population projections. From Table V we note that our population is expected to increase by almost 13 per cent over the 1950 level with "full-employment" output increasing about 46 per cent. If "full employment" is to be maintained, Gross National Product per capita will have to increase about

30 per cent over the 1950 level. A 30 per cent increase during the 1950 decade would imply a 2.66 average annual rate of growth (a somewhat smaller average annual rate of growth of 2.47 per cent is implied during the second half of the decade).

A superficial examination of Tables IV and V, would lead to the conclusion that we could expect 1955–1960 to be a period of "full employment" (consistent, with the assumptions developed above) if a rate of growth somewhat greater than the 1910–1950 period but less than the 1939–1950 period could be maintained. In the light of the recent high growth rates (especially the 1950–1952 rate of 5.5 per cent) the 1955–1960 required 3.9 per cent rate of growth seems to appear reasonable. Indeed, even the 4.3 per cent 1950–1955 rate does not seem unreasonable. Table IV, however, does not offer a complete picture. It would be foolhardy to attempt any projection based on recent high growth rates without carefully analyzing the nature of each of the component demands which comprise aggregate demand (GNP). Before we may attempt to measure the feasibility of attaining our required growth rates we must answer a series of related basic and crucial questions. For example: (1) What portion of our recent high levels of aggregate demand represents "one time" nonrecurring demand, and what portion represents demands which might be expected to continue through the 1950–1960 decade? (2) To what extent has the recent high level of government (defense) expenditures directly and indirectly created "a temporary short term upsurge" in Gross National Product? (3) Will there be sufficient private (consumer and business) demand to maintain a high level of Gross National Product when the direct and indirect influences of government spending level off and decrease?

TABLE V.—GROSS NATIONAL PRODUCT PER CAPITA

	GNP (1951 billions)	Population (millions)	GNP per Capita (1951 dollars)	GNP	Population (1950=100)	GNP per Capita
1950	303.3	151.7	1999	100.0	100.0	100.0
1955	374.3	163.2	2294	123.4	107.6	114.7
1956	388.5	164.9	2356	128.1	108.7	117.8
1957	401.2	166.5	2409	132.3	109.8	120.5
1958	414.3	168.1	2464	136.6	110.8	123.2
1959	428.7	169.7	2526	141.3	111.9	126.4
1960	443.4	171.2	2590	146.2	112.8	129.6

These are only a few of the many questions which must be answered before we can appraise the probabilities of attaining "full employment."

Part III will offer a systematic analysis of the future demand for various Gross National Product components. As we have already noted (page 862) the part played by government both as an "employer" and a "consumer" will be held to a minimum.

III. *The Structure of Demand 1955–1960*

Three sets of demand projections will be developed in this section. The first set of estimates (Variant I) represent projections of the maximum levels of demand we might expect if the high growth rates of the last decade continue. These projections will be developed below in detail. Variants II and III will represent medium and low level demand projections, respectively. These alternate projections will be developed from the Variant I projections by merely changing the basic assumptions underlying their derivation.

It should be emphasized that these demand estimates are not intended as forecasts, but rather as projections of the most probable levels of demand associated with each of the various assumptions noted below.

In Part II we developed a set of estimates of the total output (supply) of the economy under conditions of "full employment." The demand estimates developed below are, in effect, complements of these supply estimates. They are intended to answer the question, "How much can we expect the economy to absorb (demand) during a period of high level economic activity?"

Personal Consumption Expenditures 1955–1960

Projected levels of personal consumption expenditures which we might expect under conditions of high employment (if the consumption trends of the last two decades continue) are based upon (a) projected levels of per capita consumption, showing an improvement in the standard of living, and (b) projected increases in the population. Per capita personal consumption expenditure rates have been projected on the basis of a time series analysis of the personal consumption expenditure data contained in Table XXX of the National Income Supplement of the *Survey of Current Business*.[6] For the purpose of analysis each of the 178 categories of consumption expenditure listed in that table have been aggregated into ten broad consumption classifications, as shown in Table VI.[7]

[6] U. S. Department of Commerce, Office of Business Economics, *National Income and Product of the United States 1929–1950* (Washington, 1951), pp. 192–99. (See also, *Survey of Current Business*, July 1952, pp. 24–25.

[7] Of the 178 items listed in Table XXX of the National Income Supplement, 53 are included in the first nine classifications, and account for almost 92 per cent of total personal consumption expenditures. The remaining 125 items are included in a tenth, residual classification, "Other Consumption." "Food I" includes food purchased for off-premise consumption, and food produced and consumed on farms. "Food II" includes purchased meals and beverages,

TABLE VI.—PERSONAL CONSUMPTION EXPENDITURES BY CONSUMPTION COMPONENT
(1951 dollars per capita)

	Actual	Projected					
	1951	1955	1956	1957	1958	1959	1960

Total	1347	1550	1594	1637	1679	1727	1772

Consumption expenditures for each of the ten classifications were computed annually from 1929 through 1951. These current dollar series were then adjusted to take into account changes in the price level and our increasing population, and an exponential trend ($Y_c = ab^x$) was fitted to each of the constant dollar per capita consumption series.[8] Table VI

and food furnished government and commercial employees. "Miscellaneous I" includes tobacco products and smoking supplies, toilet articles and preparations, lighting supplies, cleaning and polishing preparations, miscellaneous household paper products, telephone, postage, drug preparations and sundries, physicians and dentists, privately controlled hospitals and sanitariums, purchased local transportation (less taxicab fares), gasoline and oil, automobile insurance (net payments), motion pictures, magazines, newspapers, etc., and religious and welfare activities. "Miscellaneous II" includes cleaning, dyeing, pressing, etc., laundering in establishments, barber shop services, beauty parlor services, baths and masseurs, total personal business expenditures, automobile repair, greasing, etc., nondurable toys and sport supplies, and private education and research. "Supernumerary Durables" include such items as jewelry and watches, refrigerators, washing and sewing machines, miscellaneous electrical appliances, radio and television receivers, new cars and net purchases of used cars.

[8] The resulting trend equations are as follows:

Food I	$Y_c = 227\ (1.0211)^x$	III:I
Food II	$Y_c = 49\ (1.0384)^x$	III:II
Clothing	$Y_c = 99\ (1.0182)^x$	III:III
Housing	$Y_c = 87\ (1.0385)^x$	III:IV
Fuel, Power and Light	$Y_c = 27\ (1.0242)^x$	III:V
Housefurnishings	$Y_c = 33\ (1.0254)^x$	III:VI
Miscellaneous I	$Y_c = 114\ (1.0240)^x$	III:VII
Miscellaneous II	$Y_c = 79\ (1.0175)^x$	III:VIII
Supernumerary Durables	$Y_c = 43\ (1.0473)^x$	III:IX
Other Consumption	$Y_c' = 71\ (1.0184)^x$	III:X

where Y_c = the trend value of per capita constant dollar consumption
X = the year minus 1929 (the year minus 1939 for equation III:IV)

All of the above equations with the exception of equation III:IV are fitted to 1929–1951 data. Equation III:IV is fitted to 1939–1951 data. Equations III:I and III:VIII have been adjusted to allow greater weight to post 1939 consumption trends.

presents a set of per capita consumption projections generated from the ten trend equations. It should be emphasized that these projections are not intended as forecasts, but rather as estimates of the per capita levels of consumption we might expect in a period of "high level employment," if the consumption trends established above continue.

The per capita consumption estimates, Table VI, may be converted to annual expenditure estimates by merely multiplying each per capita estimate by an appropriate population estimate. Table VII shows the

TABLE VII.—PERSONAL CONSUMPTION EXPENDITURES BY CONSUMPTION COMPONENT

(billions of 1951 dollars)

annual expenditure equivalent of Table VI (per capita consumption times the appropriate Bureau of the Census revised medium series population projection, see Table V).

The Demand for Private Residential Construction, 1955–1960

Table VIII shows the development of total nonfarm housing needs from 1955 through 1960. The data used in this table are based on the 1950 Census of Housing.[9] The total potential housing need during the 1955–1960 period is estimated at 7200 thousand housing units.

Although the annual levels of residential construction can be expected to fluctuate from year to year, we will simply assume one-sixth of the 7,200,000 required units will be constructed annually through the six-year period.

To convert the housing unit estimates into "dollar value of the construction" estimates we assume that the price of an "average housing unit" will be 9300 constant (1951) dollars. This average price estimate assumes that the 1955–1960 cost of an "average housing unit" will be

[9] U. S. Bureau of the Census, 1950 Census Population and Housing, *Housing* Vol. I, *General Characteristics*, "Part I." (Washington, 1953). See also footnote 11.

TABLE VIII.—TOTAL POTENTIAL NONFARM HOUSING NEEDS 1955–1960
(thousands of housing units)

Household Formation, March 1950–July 1960	7,270
Replacement Needs:	
Dilapidated Units in Use, 1950	2,500
One Third of the Units Which Will Become Dilapidated during the Decade	470
Losses from Disaster	250
Removal of Temporary Public Housing	600
Removal of Three Quarters of the Marginal Dwelling Units Added during the 1940's	520
Reconversion of One Third of the Apartment Conversions Added in the 1940's	600
Requirement to Establish a 4 per cent Vacancy Ratio for Rent or Sale	990
Total Potential Housing Needs 1950–1960	13,200
Less: Estimated Housing Starts 1950–1954	6,000
Total Potential Housing Needs 1955–1960	7,200

about five per cent lower than that of an "average housing unit" during the 1950–52 period. Since this average cost is expressed in 1951 dollars the projected decrease reflects an anticipated change in the "product mix" of the average, *i.e.*, a trend toward fewer high-price and greater low-price units. Table IX shows the derivation of the annual average nonfarm construction estimate for the 1955–1960 period.

TABLE IX.—AVERAGE ANNUAL EXPENDITURES FOR NONFARM RESIDENTIAL CONSTRUCTION 1955–1960

Total Potential Housing Needs 1955–1960	7,200,000 housing units
Average Annual Potential Housing Needs 1955–1960 (7,200,000/6)	1,200,000 housing units
Estimated Average Cost per Unit	9,300 1951 dollars
Average Annual Expenditure for Nonfarm Residential Construction [(1,200,000) (9,300)]	11.2 1951 billions

In addition to the estimated 11.2 billion dollar outlays for new nonfarm residential construction we can expect about another 1.0 billion dollars a year will be spent on additions and alterations of existing units. Farm residential construction is estimated at about 800 million dollars a year. Table X shows the average annual expenditures for residential construction through the 1955–1960 period.

TABLE X.—AVERAGE ANNUAL EXPENDITURES FOR RESIDENTIAL CONSTRUCTION 1955–1960
(1951 billions)

Nonfarm Residential Construction	11.2
Additions and Alterations	1.0
Farm Residential Construction	.8
Total Residential Construction	13.0

Producers' Durable Equipment and Nonresidential Construction 1955–1960

If the recent past trends in the interrelationship between (a) productivity and the stock of producers' durable equipment per worker, and (b) the stock of nonresidential construction and the stock of producers' durable equipment continue through the 1960 decade we may expect a high level of investment through the 1955–1960 period. Table XI shows the projected demand for producers' durable equipment and nonresidential construction.

TABLE XI.—THE DEMAND FOR PRODUCERS' DURABLE EQUIPMENT AND NONRESIDENTIAL CONSTRUCTION 1955–1960

(1951 billions)

	Producer's Durable Equipment	Nonresidential Construction	Total
1955	29.5	11.8	41.3
1956	34.3	13.3	47.6
1957	34.2	13.0	47.2
1958	35.6	13.5	49.1
1959	39.2	14.1	53.3
1960	40.7	14.1	54.8

The estimates in Table XI were developed in the following manner. A set of estimates of the stock of nonresidential construction and producers' durable equipment through the 1929–1952 period was derived through the use of a perpetual inventory method[10] assuming a forty-year straight line economic life for nonresidential construction and a fifteen-year straight line economic life for producers' durable equipment. The interrelationship between productivity and the stock of producers' durable equipment per worker (excluding government workers) was determined by fitting the simple linear regression equation,

$$P = a + b \cdot S/W \qquad \text{III:XI}$$

where:

P = productivity, in terms of constant dollar Gross Private Product per man-hour labor input

S = the stock of producers durable equipment

W = the number of private (nongovernment) workers

a and b are regression coefficients,

to ten annual observations covering the 1939–1941, 1946–1952 periods. A simple least-squares technique yielded the following results:

[10] Raymond W. Goldsmith, "A Perpetual Inventory of National Wealth," *Studies in Income and Wealth*, Vol. XIV, National Bureau of Economic Research (New York, 1952), pp. 6–73, especially pp. 14–17.

$$P = 1.16 + .000531927\ S/W \qquad \text{III:XII}$$
$$(r = .9840,\ r^2 = .9683,\ S_y = .049)$$

Given a productivity projection, equation III:XII may be solved for S/W to estimate the stock of producers' durable equipment required per worker to maintain the stipulated level of productivity.

$$S/W = \frac{P - 1.16}{.000531927} \qquad \text{III:XIII}$$

If we substitute a weighted average (weighted by the total hours worked) of the productivity projections given in Table II above into equation III:XIII, we may develop a projection of the stock of producers' durable equipment per worker required to maintain the secular increase in productivity projected in Part II (see Table XII). To arrive

TABLE XII.—THE ANNUAL DEMAND FOR PRODUCERS' DURABLE EQUIPMENT 1955–1960

	1955	1956	1957	1958	1959	1960
Gross Private Product per Man-Hour Labor Input (1951 dollars)	2.83	2.91	2.98	3.06	3.14	3.23
Stock of Producers' Durable Equipment per Worker[a] (1951 dollars)	3140	3290	3422	3572	3722	3892
Projected Number of Nongovernment Workers[b] (millions)	58.5	59.9	61.1	62.0	63.3	64.1
Total Stock of Producers' Durable Equipment (1951 billions)	183.7	197.1	209.1	221.3	235.5	249.3
Net Annual Expansion Requirement (1951 billions)	9.9	13.4	12.0	12.2	14.2	13.8
Replacement Requirement—Pre-1953 Equipment (1951 billions)	15.9	15.2	14.2	13.1	12.3	11.6
Replacement Requirement—Post-1953 Equipment (1951 billions)	3.7	5.7	8.0	10.3	12.7	15.3
Total Requirement (1951 billions)	29.5	34.3	34.2	35.6	39.2	40.7

[a] From equation III:XIII.
[b] From Table I.

at an estimate of the total stock of producers' durable equipment required we merely multiply the projected per worker requirements by a projection of the number of nongovernment workers.

The total demand for producers' durable equipment is equal to the net annual requirement (for expansion) plus the "depreciation" accrued on the already existing stock of equipment (for replacement). Table XII shows the projected annual demand for producers' durable equipment based on the net annual requirements shown above and a fifteen-year straight line economic life depreciation assumption. (Note: The pre-

1953 replacement requirement represents an uncentered fifteen-year moving average of constant dollar expenditures for producers' durable equipment. The post-1953 requirement represents one-fifteenth of cumulated expenditures beginning with 1953.)

Throughout the postwar (1947–1952) period a high correlation was observed between the total stock of producers' durable equipment and the total stock of nonresidential construction. This interrelationship is best described by the simple regression equation.

$$C = a + b\,S \qquad \text{III:XIV}$$

where:

C = total stock of non-residential construction
S = total stock of producers' durable equipment
a and b are regression coefficients

If we apply a simple "least squares technique" to six annual postwar observations (1947–1952) equation III:XIV becomes,

$$C = 93.185 + .3959\,S \qquad \text{III:XV}$$

$$(r = .9935,\ r^2 = .9870,\ S_y = .698)$$

From equation III:XV we can, given a projection of the stock of producers' durable equipment, estimate the required stock of nonresidential construction. Table XIII shows the stock of nonresidential construction required (from equation III:XV) to support the stock of producers' durable equipment indicated in Table XII, and also shows

Table XIII.—The Annual Demand for Nonresidential Construction 1955–1960
(1951 billions)

	1955	1956	1957	1958	1959	1960
Stock of Nonresidential Construction[a]	165.9	171.2	176.0	180.8	186.4	191.9

Replacement Requirement (Pre-1953 Construction)	7.3	7.1	7.0	6.8	6.7	6.5
Replacement Requirement (Post-1953 Construction)	.6	.9	1.2	1.5	1.8	2.1
Total Requirement	11.8	13.3	13.0	13.5	14.1	14.1

[a] Obtained by substituting the stock of producers' durable equipment projected from Table XII into equation XI:XV.

the projected annual demand for nonresidential construction on the basis of these requirements together with a replacement requirement based on a forty-year straight line economic life depreciation assumption.

Business Demand for Inventories 1955–1960

The projected demand for inventories (the net change in business inventories) represents the first differences of a total inventory series developed by substituting the projected values of Gross National Product (Table III) into a simple regression equation describing the 1947–1952 interrelationship between total business inventories and Gross National Product (see Table XIV).

TABLE XIV.—NET CHANGE IN BUSINESS INVENTORIES 1955–1960
(1951 billions)

1955	+2.7	1958	+2.7
1956	+2.8	1959	+2.8
1957	+2.5	1960	+3.0

Net Foreign Investment 1955–1960

Our projections of the level of net foreign investment (Table XV) merely represent a consensus of the most recent available "expert opinion." They reflect the impact of the assumed gradual curtailment of government foreign aid spending (as indicated under the government demand sections of this paper).

TABLE XV.—NET FOREIGN INVESTMENT 1955–1960
(1951 billions)

1955	1.0	1958	1.7
1956	1.3	1959	1.9
1957	1.5	1960	2.0

The Demand of the Federal Government 1955–1960

Estimates of the demand of the federal government from 1955 through 1960 have been projected in two broad components, wages and salaries of government workers, and purchases from business (see Table XVI). The wages and salaries projections are taken from Table III. Federal government purchases from business are projected in three categories: national defense, other national security, other nondefense expenditures.

National defense purchases from business are based on the assumption that the average expenditure per member of the armed forces will be about 25 per cent higher than it was during the 1947–1950 period. The 1947–1950 period average (3970 1951 dollars) was developed by dividing national defense expenditures minus the sum of the payrolls of the armed forces plus the payrolls of the civilian employees of defense activities by the number of members of the armed forces. Other federal

TABLE XVI.—GOVERNMENT PURCHASES OF GOODS AND SERVICES 1955–1960
(1951 billions)

[a] State and local government product, Table III.
[b] Based on an assumed annual expenditure per worker of $1,250 in 1955 and an annual increase of $10 each year thereafter.

government purchases from business are projected on the assumption that they will be 15 per cent lower per general nondefense civilian worker than they were during the 1947–1950 period.

The Demand of State and Local Governments 1955–1960

Table XVI also shows the projected demand of state and local governments through the 1955–1960 period. The demand for personal services (wages and salaries) is taken from Table III. Purchases from business are based on the annual expenditures per state and local government worker during the 1946–1951 period adjusted to take into account a gradual secular "improvement" in the services provided by government. The projected expenditures for public works are extremely high and are without historical precedent. They are based on the estimates contained in *The Sustaining Economic Forces Ahead*,[11] assuming the "demand" for public works will be almost completely fulfilled during the 1950–1960 decade.

Table XVII summarizes the demand projections developed in Tables VI through XVI. The Variant I estimates assume a continuation of the recent high growth rates considered in detail in the preceding sections. Our Variant II and Variant III demand projections merely assume an

[11] Joint Committee on the Economic Report, *The Sustaining Economic Forces Ahead* (Washington, 1952), pp. 34–59. (See also, Federal Reserve Bank of Chicago, *Business Conditions*, Jan. 1953, pp. 12–15.)

across-the-board decline in the over-all growth rate, to a rate three-quarters, and one-half, the Variant I rate, respectively.

TABLE XVII.—THE STRUCTURE OF DEMAND 1955–1960

(billions of 1951 dollars)

	1955	1956	1957	1958	1959	1960
Variant I						
Personal Consumption Expenditures	253.0	262.8	272.8	282.2	293.0	303.4
Residential Construction	13.0	13.0	13.0	13.0	13.0	13.0
Producers' Durable Equipment	29.5	34.3	34.2	35.6	39.2	40.7

Net Foreign Investment	1.0	1.3	1.5	1.7	1.9	2.0
Government Purchases of Goods and Services	75.6	71.7	68.5	66.6	63.1	61.3
Total Demand	386.6	399.2	405.5	415.3	427.1	437.5
Variant II—Total Demand	372.3	381.4	385.9	392.9	401.3	408.6
Variant III—Total Demand	357.8	363.6	366.5	370.9	376.2	380.8

IV. *"Full Employment" 1955–1960*

This section will compare the "supply" projections developed in Part II with the "demand" projections developed in Part III. The supply estimates were based on a 97.5 per cent employment assumption; that is to say, they represent a projection of the levels of output required to provide employment for 97.5 per cent of the total civilian labor force. Frictional unemployment has been taken as 2.5 per cent. The 2.5 per cent level is somewhat arbitrary: it is based on consideration of the factors listed in *Employment and Unemployment.*[12]

TABLE XVIII.—EXCESS (+) OR DEFICIT (−) SUPPLY OVER DEMAND 1955–1960

(billions of 1951 dollars)

	Variant I Demand	Variant II Demand	Variant III Demand
1955	−12.3	+ 2.0	+10.5
1956	−10.7	+ 7.1	+24.9
1957	− 4.3	+15.3	+34.7
1958	− 1.0	+21.4	+43.4
1959	+ 1.6	+27.4	+52.5
1960	+ 5.9	+34.8	+62.6

We are now concerned with determining the "actual" levels of unemployment implicit to each of our three demand variants. Table XVIII

[12] Joint Committee on the Economic Report, *Employment and Unemployment* (Washington, 1950), pp. 56–97. (See also, A. J. Jaffe and C. D. Stewart, *Manpower Resources and Utilization* [New York, 1951], pp. 78–85, 477–84.)

compares each of the three "demand" variants with the "full-employment supply" estimates shown in Table III.

In the present model, the interrelationship between supply (S), demand (D) and the employment ratio (E_R) may be defined as follows:

When

$$S \equiv D, \quad E_R \equiv .975 \qquad \text{(IV:IA)}$$

$$S < D, \quad E_R > .975 \qquad \text{(IV:IB)}$$

$$S > D, \quad E_R < .975 \qquad \text{(IV:IC)}$$

To determine the "actual" level of unemployment associated with each of the three demand variants we must convert the excesses and deficits shown in Table XVIII to an employment equivalent. That is to say, we must "cost out" the employment equivalent of one billion dollars of demand. Once we have determined the average annual output per worker (Z_A), one billion dollars worth of employment (E_B) becomes,

$$E_B = \frac{\text{1 Billion Dollars}}{Z_A} \qquad \text{IV:II}$$

The average annual output per worker, for agricultural and non-agricultural workers, was shown in Table II; Table XIX shows the average annual output per *average* (weighted average of agricultural and nonagricultural workers) worker and the associated value of E_B for the 1955–1960 period.

TABLE XIX.—AVERAGE ANNUAL OUTPUT PER WORKER AND EMPLOYMENT 1955–1960

	Average Annual Output per Worker(Z_A) (1951 dollars)	Employment per Billion Dollars of Demand (E_B) (thousands of workers)
1955	5872	170.3
1956	5992	166.9
1957	6106	163.8
1958	6236	160.4
1959	6352	157.4
1960	6499	153.9

Once we have established values for E_B we may convert the dollar estimates, Table XVIII, into "employment equivalents." Table XX shows the "employment equivalents" of the excess or deficit demand of Table XVIII. Table XX also shows the total unemployment (by combining the employment equivalents of the excess or deficit demand with the minimum frictional unemployment assumed in the construction of

TABLE XX.—THE EFFECT OF EXCESS (+) OR DEFICIT (−) DEMAND ON EMPLOYMENT 1955–1956

	1955	1956	1957	1958	1959	1960
Employment Equivalents of Excess or Deficit Demand Shown in Table XVIII						
Variant I Demand (million workers)	+2.1	+1.8	+ .7	+ .2	− .3	− .9
Variant II Demand (million workers)	− .3	−1.2	−2.5	−3.4	−4.3	−5.3
Variant III Demand (million workers)	−2.8	−4.2	−5.7	−7.0	−8.3	−9.6
Minimum Frictional Unemployment[a] (million workers)	1.6	1.7	1.7	1.7	1.8	1.8
Unemployment						
Variant I Demand (million workers)	—[b]	—[b]	1.0	1.5	2.1	2.7
Variant II Demand (million workers)	1.9	2.9	4.2	5.1	6.1	7.1
Variant III Demand (million workers)	4.4	5.9	7.4	8.7	10.1	11.4
Unemployment as Percentage of Total Civilian Labor Force						
Variant I Demand (per cent)	− .8	− .1	1.5	2.2	3.0	3.8
Variant II Demand (per cent)	2.9	4.3	6.1	7.3	8.6	9.9
Variant III Demand (per cent)	6.7	8.7	10.8	12.5	14.2	15.9

[a] From Table I.
[b] Under the Variant I Demand assumption employment falls below the frictional unemployment minimum.

Table I) associated with each demand variant. Unemployment as a percentage of the total civilian labor force is also shown with respect to each demand variant.

It will be noted that under the Variant I demand assumptions unemployment fell below the assumed frictional minimum from 1955 through 1958, *i.e.*, demand exceeded supply. Under the Variant III demand assumptions unemployment is projected at a maximum, reaching a peak of 11.4 millions in 1960.

If we are to have "full employment" through the 1955–1960 period we must adjust "supply" to a level where "supply" is just equal to demand. Supply (S) may be expressed as a function of three factors, productivity (P) in terms of constant dollar output per worker per man-hour labor input, the number of workers (E), and the average weekly hours worked (H).

$$S = (E)(P)[(H)(52)] \qquad \text{IV:III}$$

The level of employment (E) is stipulated, *i.e.*, 97.5 per cent of the total labor force; we have assumed productivity (P) as a semi-independent function of time; any adjustments in the levels of supply, therefore, must be made by adjusting the length of the work week. When "demand" exceeds "supply" the work week must be lengthened, when "supply" exceeds "demand" it must be shortened.

To determine how much the work week must be changed we must

"cost out" the dollar value of "one hour's worth of employment." "One hour's worth of employment" may be defined by the equation

$$H_E = (P)(E) \qquad \text{IV:IV}$$

where

H_E = the dollar value of "one hour's worth of employment"
P = productivity, constant dollar output per worker per man hour labor input
E = the number of workers employed.

Table XXI shows the value of "one hour's worth of employment" from 1955 through 1960; this was determined by merely substituting the pertinent data from Tables I and XII into equation IV:IV. "One hour's worth of employment" is then converted into the hours required to produce "one billion dollars worth of supply." To determine the changes in working hours required to adjust "supply" to a level where the latter is just equal to "demand," we merely multiply the excesses and deficits shown in Table XVIII by the hours required to produce "one billion dollars worth of supply."

TABLE XXI.—WORKING HOURS REQUIRED TO MAINTAIN "FULL EMPLOYMENT"

	1955	1956	1957	1958	1959	1960
"One Hour's Worth of Employment" (millions of 1951 dollars)	182.5	191.5	199.4	207.8	217.0	226.1
Hours Required to Produce "One Billion Dollars Worth of Supply"	5.48	5.22	5.01	4.81	4.61	4.42
Changes in Average Anual Working Hours Required to Maintain "Full Employment"						
Variant I Demand	+67.4	+ 55.9	+ 21.5	+ 4.8	− 7.4	− 26.1
Variant II Demand	−11.0	− 37.1	− 76.6	−102.9	−126.3	−153.8
Variant III Demand	−90.4	−130.0	−173.8	−208.8	−242.0	−276.7
Changes in Average Weekly Working Hours Required to Maintain "Full Employment"						
Variant I Demand	+1.3	+1.1	+ .4	+ .1	− .1	− .5
Variant II Demand	− .2	− .7	−1.5	−2.0	−2.4	−3.0
Variant III Demand	−1.7	−2.5	−3.3	−4.0	−4.6	−5.3
Average Weekly Working Hours Required to Maintain "Full Employment"						
Initial Supply	39.9	39.6	39.4	39.2	38.9	38.7
Variant I Demand	41.2	40.7	39.8	39.3	38.8	38.2
Variant II Demand	39.7	38.9	38.3	37.3	36.4	35.2
Variant III Demand	38.2	37.1	36.1	35.2	34.3	33.4

From an analysis of Tables XVIII through XXI the possibility of maintaining "full employment" through the 1955–1960 period seems reasonable. Under the Variant I and II demand assumptions only a minor adjustment in the length of the average work week would be required to equate "supply" with "demand." The last four lines of Table XXI compare the average work week implicit in our initial supply projections with the average work week required to maintain "supply-demand equilibrium" under each of the three demand assumptions.

Under the Variant I and II demand assumptions the weekly hours are fairly reasonable, the maximum adjustment required being only three hours (Variant II, 1960). This adjustment may be accomplished in two ways: the average work week could be adjusted as shown, or the average length of vacations could be increased. For example, if the labor force works an average work week of 38.7 hours and a 35.2 work week is required to maintain "supply-demand equilibrium," the average worker is required not to work (be on vacation) 4.7 weeks a year.[13] Or some shortening of the average work week could be combined with a somewhat shorter vacation. For example, with an average work week of 36.7 hours the vacation would need to be 2.1 weeks; with an average work week of 36.2 hours the vacation would need to be 1.4 weeks. Such adjustments seem not at all unreasonable. However, under the Variant III demand assumptions it would be difficult, if not impossible, to balance supply with demand without drastically reducing the work week (or unreasonably increasing the length of the vacation period).

Thus far we have assumed a rather high goal (97.5 per cent) in defining "full employment." If we were willing to accept a lower employment rate, or its complement, a higher unemployment rate, "full employment" might be attained with a lower level of demand than that specified in the tables above. Table XXII shows the "demand deficits" acceptable if we define "full employment" with a lower employment rate.

If we define "full employment" at a 95.0 per cent level rather than the 97.5 per cent level assumed above we may attain "full employment" with a level of demand from 9.7 to 11.7 billion dollars below that required at the 97.5 per cent level. A 94.0 per cent "full employment" assumption would allow a deficit (below the 97.5 per cent, demand requirements) of from 13.6 to 16.3 billion dollars.

[13] A 35.2 hour work week adds up to 1830.4 hours a year (without vacation), while at 38.7 hour work week adds up to 2012.4 hours. The difference, 182 hours, is 4.7 weeks (for a 38.7 hour week). It is obvious that the three hour adjustment may not be accomplished by merely lengthening the vacation period.

TABLE XXII.—DEMAND DEFICITS IMPLICIT IN SELECTED EMPLOYMENT RATES, 1955–1960

Employment Rate (per cent)	Demand Deficit (billions of 1951 dollars)					
	1955	1956	1957	1958	1959	1960
97.5	0.0	0.0	0.0	0.0	0.0	0.0
97.0	1.9	2.0	2.1	2.2	2.3	2.3
96.5	3.9	4.0	4.2	4.3	4.5	4.7
96.0	5.8	6.1	6.3	6.5	6.8	7.0
95.5	7.8	8.1	8.4	8.7	9.0	9.3
95.0	9.7	10.1	10.5	10.9	11.3	11.7
94.5	11.6	12.1	12.6	13.0	13.5	14.0
94.0	13.6	14.2	14.7	15.2	15.8	16.3

From the above analysis the following conclusions are evident:

1. The maintenance of a high level of employment (in the neighborhood of 97.5 per cent of the total labor force) through the 1955–1960 period would require a continuation of the relatively high growth rates (in demand) of the last decade.

2. A future high level of employment is possible within the present framework of the economy (Variant I and II demand estimates).

3. A high level of employment appears possible without a high level of federal government spending.

4. Four strategic areas of demand, nonresidential construction, producers' durable equipment, consumer supernumerary durables, and state and local government public works will have to be maintained at high levels almost without historical precedent.

5. The over-all economic adjustments required to attain "full employment" appear reasonable.

On the whole, if economic stability is maintained, and the long-term growth rates in the standard of living, productivity, and capital formation continue, we may reasonably expect the last half of the 1950–1960 decade to be a period of "full employment."

COMMUNICATIONS

Additional American Reprints of Economic Writings 1776-1848

To three correspondents I am indebted for eleven titles, additional to those published in the *American Economic Review* for December, 1952. Two of them are earlier than 1776. Professor Fetter of Northwestern University has called my attention to a printing of the *Bullion Report* (1810) in the *Financial Register of the United States* in the issues of July 5 and 19, 1837 and to its issue between "hard covers" in 1874. To this evidence of interest in banking, the lack of which I found so puzzling, may be added Cobbett's *Paper against Gold* contributed, with most of the other titles, by Mr. Salkolski of *The Commercial and Financial Chronicle*. It may not be fanciful to assume that a date as late as 1874 for the printing of the *Bullion Report* shows a professional concern in the development of theory; just as continuing reissues of Say's *Treatise* and Marcet's *Conversations*, a number of which Professor Jennings of Wheaton College has noted in Hollander's catalogue, give evidence of the growth of economics as a teaching subject. I have arranged the titles chronologically and append them. My correspondents are responsible for all except the original dates of publication.

May I take this opportunity to point out the error of note** in my original article (p. 880). Jefferson did not translate but extensively revised Destutt de Tracy's work on political economy (*ibid.*, p. 877).

Welfare Comparisons and Changes in Tastes

It has frequently been noted that the "new welfare economics" operates on the working assumption that tastes do not change, or alternatively, that if they change, welfare comparisons are meaningless. This assumption has of course been given explicit attention in index number theory and in welfare theory proper, but it has not until quite lately received much emphasis in the recent upsurge of interest in welfare economics associated with such names as Arrow, Little, Samuelson, Baumol and Scitovsky.

The recent review by I.M.D. Little of Arrow's *Social Choice and Individual Values*[1] brings the assumption into relief by relating it to Arrow's pioneer work. And more recently, Sidney Schoeffler in an interesting paper,[2] whose point of departure is also Arrow's book, examines the whole question of changes in tastes and the ability to make welfare judgments. In addition, he advances two methods by which welfare judgments might be made in a setting in which individual tastes change, and frequently.

My major purpose is to offer a modification of one of Schoeffler's suggested comparison methods in a way which I think might justifiably increase the frequency of unambiguous responses rendered by it.

The framework within which Schoeffler advances his suggestions may be briefly sketched. Consider an individual at two periods of time. At t_0 the social state (the matrix showing the distribution of all goods and services, the political situation, the social welfare function, etc.) is A, at t_1 it is B. If the individual's tastes are unchanged, he can say with consistency both at t_0 and t_1 whether he prefers A to B, B to A, or is indifferent between them. He therefore can say at t_1 whether or not he is better off than at t_0; and his answer will be the same as when he is asked at t_0 where he would be better off (*i.e.*, if B were expected to exist at t_1).

Similarly, every other individual in the community can be conceived of as capable of making the same comparison. On the basis of these individual comparisons, it is possible to conceive of a social comparison which "reflects" these individual comparisons.[3] On the basis of the rule for deriving the social

[1] *Jour. Pol. Econ.*, Oct. 1952, LX, 422-32.

[2] "Note on Modern Welfare Economics," *Am. Econ. Rev.*, Dec. 1952, XLII, 880-87.

[3] Neglecting Arrow's "Possibility Theorem" which states that if the social comparisons are asked to fulfill certain apparently reasonable conditions of correspondence with the individual comparisons, then no method of arriving at such social comparisons exists.

from the individual comparisons, we can say that society at t_1 is better off than, worse off than, or as well off as, at t_0.

But this last comparison and all the comparisons on which it is based depend on the tastes of the various individuals being unchanged at the two moments in time. If tastes change, then some individual might well say at t_1 that he prefers B to A while at t_0 say that he prefers A to B. Which statement is correct? The economist claims to be unable to find out. He characterizes the comparisons as meaningless—thus, Schoeffler says, "It is meaningless . . . for the reader to ask himself whether he is more or less happy now than he was at four years old."[4] And the social comparisons based on the individual comparisons he similarly characterizes as meaningless.

We may summarize the above using the terminology of social welfare functions: Expressing tastes solely in terms of individual orderings[5] of the alternative social states, the social welfare function is a rule by which we derive a social ordering corresponding to each set of individual orderings. The social ordering is a function of the several individual orderings. Given a particular set of individual orderings, we obtain a particular social ordering; and so long as this particular set of individual orderings remains unchanged, we can compare the welfare of any individual or of the group itself under various actual alternative social states. If any of the individual orderings change, we will have a new set of orderings and can obtain a new social ordering, whereby, so long as the new orderings remain unchanged, we may from this single new vantage point make actual welfare comparisons between alternative social states. But when these orderings change, comparison of the affected individuals' or of the group's welfare under a social state when one set of orderings prevailed, with the social state when another set of orderings prevailed, is meaningless. Under the circumstances envisaged by Schoeffler, moreover, any change in the environment changes with it some individual orderings. A given set of orderings will prevail for one social state only, and when this state changes to the one with which it is to be compared, the set of individual orderings will also have changed. So it seems that we are left with no consistent criterion for making *any* actual comparisons.[6]

Schoeffler suggests that, even under the transitoriness of individual orderings, unambiguous welfare conclusions can sometimes be drawn by a slight modification in the definition of welfare change. His proposed treatment resembles Scitovsky's famous double criterion for judging changes in social welfare under alterations affecting income distribution. An individual is to compare social states A and B. Consider his comparison on the basis of the ordering which prevailed under both of the social states. Thus, for example, if he preferred A when A existed in fact and also after the change to B, then

[4] Schoeffler, *op. cit.*, p. 883.

[5] More complicated functions typically imply cardinal properties of utility.

[6] Anticipatory comparisons are of course possible, whereby *hypothetically* different social states are compared with the prevailing state; but these comparisons are without practical importance for our present purposes, since an alternative state conceived of cannot come into existence without changing some individual's ordering and making his original judgment inconsistent.

the change to B decreased his welfare. Similarly, if he preferred B both before and after the change to B, then he benefited from the change. If he preferred A before the change and B after, then Schoeffler defines the change as "welfare-neutral." If he preferred B before the change and A after, then Schoeffler defines the change as "welfare-abortive." These last two concepts essentially mean that only ambiguous conclusions can be drawn.

The crucial aspect of this method seems to me to be that prechange and postchange orderings are symmetrically weighted in deriving welfare conclusions. This is very likely an unobjectionable device for posing the general case; but I would suggest that there is an important subset of all cases where individual orderings change for which a lack of symmetry might be appropriate, and might, indeed, enable unambiguous welfare conclusions to be given more frequently than with symmetry.

One of the most important reasons for individual orderings to change is the accumulation of experience with old and new commodities which the consumer gains. Experimentation with familiar goods and services ordinarily enables the consumer better to evaluate how they satisfy him—enables him *more accurately* to order them *in accordance with unchanged underlying propensities*. Similarly, experience with new commodities does not ordinarily signify changes in the personality make-up of the consumer; but it does give him an opportunity not previously possessed to establish a consumption pattern closer to his essentially unchanged criterion of what is desirable. Schoeffler implicitly recognizes this phenomenon when he points out that "a person's attitude toward goods is determined in large measure by the assortment of goods which is *at present* in the visual field of the individual."[7] Attitudes toward goods are determined largely by one's experience of them—all other aspects of the personality unchanged.[8]

So, in the light of experience with various commodities, a consumer's orderings of social states will change. But because these changes are the results of learning, they are irreversible. Consider the model formulated by Schoeffler. Any action (or policy) which changes the social state will in general bring about also a change in some individual orderings. We desire to draw welfare conclusions about the change from state A to state B. Under State A, the individual's ranking is R_i^j, by which he prefers B to A; under B, it is R_i^k by which he prefers A to B. Schoeffler, treating R_i^j & R_i^k symmetrically, draws the conclusion that the change is "welfare-abortive" (an ambiguous conclusion). Can we *meaningfully* lessen the ambiguity? I suggest so.

If the change from R_i^j to R_i^k represents the clarification, the learning from experience about different types and combinations of commodities, then: (1) a change back from state B to state A would not result in a similar change from R_i^k to R_i^j; (2) A would have been preferred by the i'th individual over B both after and before the change if he had known more about B before the change; and this is testified to by our expectation that in the event of a

[7] P. 882. Italics mine.

[8] Georgescu-Roegen devotes substantially the whole of his admirable article, "The Theory of Choice and the Constancy of Economic Laws," to the implications of this factor for demand theory. *Quart. Jour. Econ.*, Feb. 1950, LXIV, 125-38.

change back to B, he would probably still prefer A, thereby enabling us to render in that event an unambiguous welfare conclusion that welfare is greater at A than at B.

Can we not, with this illustration in mind, feel justified in dropping the double ordering perspective when changes in orderings reflect trial and error approximations to an unchanged underlying predispositional scale? Our procedure, where justifiable, would be simply to evaluate the given change in terms of what Schoeffler calls the *ex post* ordering alone (R_i^k in our illustration), and would thereby enable us to draw unambiguous welfare conclusions.

Two related problems present themselves. First, how can one empirically tell when a particular change in some individual's orderings fulfills the characteristics described here? To be sure, no ordering change is due solely to clarification. All education changes the individual in some way. But modern psychology promises an ability in the not too distant future to limn empirically the major orientation patterns of an individual, and consequently to enable us to trace significant changes in these patterns. Certainly, it can not be expected that even in this near future we shall be able to separate out different kinds of changes in orderings with more than rough proximateness. But this may well provide a tolerable margin in actual empirical applications. It cannot be honestly contended that there is a much greater degree of correspondence between our present demand theory and the real world.

For our immediate purposes, however, there is the psychologists' suggestion that basic personality patterns do exist, and that they remain relatively stable through substantial portions of a person's adult lifetime. If we can accept for economic analysis the notion that the changes in orderings meriting multiple perspective weights are only those changes which reflect significant personality reorientations, then we can realistically assume "tastes" (as these basic orientations) to be constant for a much wider range of economic problems than has heretofore been possible.

The second issue raised is allied to the first, and is very serious. Why *should* economists identify tastes only as these basic orientations? Granted, where actually erroneous expectations account for some orderings, changes which reflect only a correction of such errors (let us call them "correctional changes") may appropriately be treated as approximations toward equilibrium within a stochastic conception of consumer behavior. There are, however, other changes in orderings which neither substantially represent trial and error revisions ("correctional changes") nor changes in basic personality orientations ("personality changes"). These represent moderately different ways of looking at various—even familiar—commodities; and they would seem to be exactly what economists have always referred to by the concept of "changes in tastes." Economists *have* not, in the past, restricted the concept solely to "personality changes." What justification is there now for such a restriction? If there is no justification, and one attempts actually to apply the schema presented here, then is it possible empirically to differentiate between corrective changes, which we would not want to consider changes in tastes, and those intermediate changes, which we would want to consider changes in

tastes? Finally, if we cannot in fact make this distinction but would nevertheless like to use the schema analytically, then wouldn't this practically involve dispensing with the concept of consumer equilibrium, since "equilibrating" changes could be considered as continuing indefinitely without any apparent tendency to converge?

I cannot give definitive answers to these questions. But I should like to suggest what kind of answer seems appropriate at this time.

1. There is justification for restricting the concept "changes in tastes" to "personality changes" (and thus, identifying "tastes" with basic personality orientation). This justification consists in the desirability of subsuming much of the intermediate class of ordering changes under the "corrective" category. We speak of changes in tastes as representing analytic discontinuities because they supposedly represent evaluative discontinuities for the individuals concerned. But the consumer typically does not feel such discontinuities when only minor ordering changes occur. He acts with most of them as though he had "learned better." This strongly resembles the characteristic of corrective changes. Evaluative discontinuity takes place when there is a significant change in perspective—when the consumer has experienced the change in basic personality orientation to which I have referred above as "personality change." In a real sense, then, all nonpersonality changes can usually be lumped together and simply treated as partaking more or less the character of equilibrating adjustments in the light of experience. For concrete applications, where it may be desirable to exclude ordering changes which partake "too little" of the character of "corrections," an arbitrary cut-off point can be established to suit the nature of the particular problem in hand.

2. If the procedure under (1) should prove unacceptable, and it be desirable that "intermediate" changes be included as changes in tastes, then the cut-off point mentioned above, where the change partakes "too little" of the character of correction (interpreted now more narrowly than above), assumes great analytic importance. Since the degree of "littleness" here is probably a continuum, the cut-off point will be arbitrary. But within this limitation, it seems reasonable to expect that at least a rough classification is possible by observation of consumer behavior. Interviewing studies, for example, would seem an appropriate tool for throwing light on this, since how the consumer describes his ordering change is evidence as to what kind of change it is. Reversibility or irreversibility of the ordering changes might be suggested as a useful index for classifying. Whatever the empirical means used, however, no substantial difficulties in principle suggest themselves why it should not be possible to come observationally close to any specified domain of the concept of correctional change—so long as that very domain can be operationally defined. The burden, indeed, would seem to be on the critic to say exactly what he means by the "intermediate" category.

3. Assuming that we do lump correctional with "intermediate" ordering changes, whether deliberately (as #1 argues), or inadvertently (as might occur if the argument of #2 were groundless), what becomes of the concept of equilibrium? A number of economists even now are convinced that applica-

tion of consumer demand theory to real world statistical observations requires interpreting the theory stochastically. A stochastic model postulates randomly distributed deviations from equilibrium over time, to reflect the trial and error behavior of consumers in seeking equilibrium. Thus, on this view, already current, the equilibrating process is not thought of as one of instantaneous adjustment but rather as one requiring perhaps considerable duration. It is by no means self-evident that by including "intermediate" changes as part of the random component we should be appreciably increasing the duration of the adjustment path, and thereby watering down the equilibrium concept.

It might be argued, in fact, that the proposed treatment of ordering changes strengthens rather than weakens the equilibrium concept. When "intermediate" changes are treated as changes in tastes, their supposed frequency means that before a consumer ever reaches one equilibrium he is imposing on himself the need to begin adjusting to a new one. Without the "feedback" of successfully realized equilibria to serve as incentive and guide for the consumer, the very meaning of adjustment becomes suspect; and in any case, prediction becomes hazardous for the economist in a system where initial conditions change more rapidly than ever full adjustment to old conditions can be attained. If conservation of the equilibrium concept be a legitimate methodological criterion—and of course it may not be—then lumping "intermediate" with purely correctional ordering changes would seem to possess this saving grace in at least as great a measure as existing stochastic theory.

To summarize the argument of this paper, I have in effect advanced a new definition of "tastes," under which it would be appropriate to draw unequivocal welfare conclusions even under those situations defined by Schoeffler as involving "changes in tastes." Some empirical and methodological implications of the new definition were briefly explored. It is hoped that the seemingly important analytic advantages sketched here will warrant deeper examination of this approach by others.

JEROME ROTHENBERG*

* The author is assistant professor of economics at the University of California, Riverside, effective January 1954. He wishes to express gratitude to Professors Albert G. Hart, of Columbia University, and Sidney Schoeffler, of the University of Massachusetts, for helpful comments.

A Theory of Excise Subsidies: Comment

In the September 1952 issue of the *American Economic Review,* Professor Earl R. Rolph[1] analyzes the effects of excise subsidies on product prices, money costs of production, and private money incomes and expenditures. He reaches the conclusion that in the case of a general subsidy granted to producers of all commodities at a uniform and proportional *ad valorem* rate no portion of the subsidy is shifted to consumers in the form of lower product prices; the entire amount is passed on to owners of resources (including both hired resources and resources attached to firms) in the form of higher incomes. The purpose of this comment is to point out that this conclusion depends upon additional assumptions not explicit in the analysis, and is in no sense

[1] "A Theory of Excise Subsidies," XLII, 515-27.

general. The principal point which the writer wishes to make is that in any model which embraces the whole of an economy, rigorous analysis of the effect of a new subsidy or tax is not possible unless assumptions are made with regard to *both* the expenditure *and* the receipts side of government.

This comment is confined chiefly to that portion of Rolph's analysis in which he considers a system of excise subsidies leveled at a uniform rate on all commodities. In the simple model analyzed, only two commodities, X and Y, are produced, under conditions of pure competition. Resource services are also competitively priced. Resources are fixed in amounts, and the price system is assumed to keep them fully employed. Under these conditions Rolph traces the consequences of subsidizing both commodities at the same *ad valorem* rate. No mention is made of the source of the funds out of which the subsidies are paid. During the analysis, the market demand schedules for the two commodities remain unchanged,[2] presumably indicating that buyers' disposable incomes are not altered by any immediate change in their tax burdens.

Since the subsidy is an addition to the firm's revenue per unit, its initial effect is to increase every firm's marginal revenue while leaving its marginal cost unchanged. Firms in both industries therefore seek to expand output, and increase their demands for resource services. But since output cannot be expanded, restoration of equilibrium requires an upward adjustment in the prices of resource services until "marginal costs rise and exceed market prices by the amount of the subsidy per unit at unchanged outputs." The net result: no change in the allocation of resources, no reduction in product prices; only a bidding-up of the prices of hired resources until "money costs of production are everywhere increased proportionately." Rolph notes that "these conclusions are inconsistent with those theories which hold that equivalent excise taxes are shifted to consumers."

In considering this analysis, several questions must be raised. Where does the government get the money with which to pay the subsidy? From new taxes? Evidently not—at least, initially. If new *indirect* taxes had been imposed, they would have affected the price of X or Y (since there are no other commodities to tax) and would have canceled, either wholly or partially, the effect of the subsidy—and no such offsets are noted in Rolph's analysis. Nor could new *direct* taxes have been imposed, since such a method of financing would reduce disposable incomes, shift market curves downward, and thus cause product prices to fall.[3] If, in an economy in which buyers' outlays for commodities X and Y exhaust their incomes,[4] new direct taxes were imposed equal to the subsidy payments, the market prices of X and Y would have to

[2] Rolph employs the device of considering a subsidy as a supplement to the price received by the seller rather than as a deduction from his cost. From the seller's standpoint, therefore, the subsidy shifts the demand curve. But the prices which buyers are willing to pay for various outputs remain unchanged.

[3] Direct taxes which absorb only loanable funds, leaving consumption funds undiminished, are conceivable, but are out of the question here since, in the model being discussed, "the resources employed to produce the two commodities exhaust the resources available to the economy"—that is, there is no net investment, no unemployment, and therefore, in the absence of deflationary or inflationary price movements, no net saving or dissaving.

[4] As stated in the preceding footnote, saving is zero in the model under consideration.

be reduced by an amount equal to the subsidy rate in order that output remain at the full-employment level. But if new taxes are not imposed, what method of government financing is employed? And since the subsidy has "a positive income effect with respect to all owners of resources," why does not the rise in their incomes cause them to increase their demands for X and Y? Somewhere among Rolph's implicit assumptions must be one that keeps the market demand schedules from changing.

In the absence of additions to tax revenue, the money used to pay the subsidies must come from one or more of the following sources: (1) drawing down of government bank balances, (2) printing new money, (3) credit-expansionary borrowing from the banking system, (4) borrowing from the public. The first three methods increase the purchasing power in the hands of the public, and may be described for our purposes as inflationary monetary expansion. The fourth method introduces new complications into the analysis, since its effects depend upon conditions with regard to such things as liquidity preference, interest rates, the rates of new saving and investment (if any), etc.; but if we restrict ourselves to the simplest case, where saving and investment are initially nil, so that government borrowing from the public must reduce consumption outlays by an equal amount, we can consider borrowing from the public as equivalent to taxation in its effect on demand. We may therefore group the sources of government funds into two categories: (a) withdrawal of consumption funds through taxation or borrowing, and (b) money creation.

Let us assume provisionally that the government subsidies consist of new money pumped into the system. The initial maintenance of demand for X and Y is now explained. But the final equilibrium would not be that of Rolph's analysis. The rise in incomes would shift demand schedules for both X and Y. Moreover, incomes would not reach a new equilibrium at a higher level, but would continue to rise so long as the inflationary method of financing continued. An equilibrium position is attainable only when government revenues (through taxation and/or borrowing from the public) rise sufficiently to offset exactly the rise in government payments due to the new subsidies.

The conclusion is inescapable that Rolph's model operates in the way he describes only when the following assumption is made: that aggregate tax receipts remain unchanged so long as aggregate income remains unchanged, but rise whenever aggregate income rises by an amount just sufficient to keep aggregate disposable income from rising. This assumption could be fulfilled if it were supposed that the taxing authorities made successive increases in tax rates as aggregate income rose. If this clumsy hypothesis is to be avoided, the only possible alternative is to assume that income tax rates are so steep that the tax rate on increments to income is 100 per cent. Only under such conditions would the higher money incomes be prevented from pushing upward the demand curves for X and Y.[5] Under less confiscatory tax rates (*e.g.*, those of

[5] Since saving and investment are nonexistent in the model being discussed, and since indirect taxation is ruled out by the nature of the problem, it is being assumed that all taxes are consumption-reducing taxes. The general argument being presented, however, does not depend on such an assumption. Even if saving and investment were introduced

the United States) income would have to rise several times the amount of the subsidy before the additional tax revenues rose sufficiently to halt the price-income spiral caused by the "deficit financing" character of the subsidy program. It is therefore not generally true that the final income effect is quantitatively equal to the amount paid by the government in the form of subsidies; the final income effect depends on the tax system: on how high the tax rate on incremental income is, and whether or not tax rates are changed.

Let us consider briefly four possible situations, in each of which it will be supposed that all disposable income is spent on X and Y in some fixed proportion (which means that the demand prices of X and Y at full-employment output vary directly with aggregate disposable income), and that government receipts and payments are in balance before the subsidy and new tax are put into effect.

1. Suppose, along with the subsidy, a new direct tax independent of income (for example, a property tax), continually subject to adjustment so that it is at all times just sufficient to defray the entire expense of the new subsidy program.[6] Suppose also that the tax system includes an income tax, so that the government's revenue is some function of aggregate income. Disposable income falls by the amount of the new tax. With their purchasing power reduced, people demand less of X and Y at current prices. The prices of X and Y must fall until the revenues of firms in the two industries have fallen by the amount of the new tax. Since the new tax receipts and subsidy payments are equal, product prices fall by the amount of the subsidy per unit. In this situation there is no income effect; the entire subsidy is shifted to consumers.

To make this point clear, imagine some part of the subsidy shifted to owners of resources, so that the prices of X and Y are higher than under the equilibrium just described. Income tax receipts would then be higher. Disposable incomes would not be sufficiently higher to raise the demand price of each commodity by the full amount by which unit payments to owners of resources were increased. The price could not be maintained at this higher level; it would fall, and continue to fall so long as government receipts exceeded payments. Equilibrium is possible only when the income effect of the subsidy is wholly obliterated.

2. Suppose now the same situation, except that the new tax brings in a constant amount just sufficient to defray the expense of the subsidy *at present product prices*. In this situation, too, the prices of X and Y fall. As they fall, the subsidy payments per unit of X and Y fall, so that total government payments become less than total government receipts. The budget surplus thus created has a further deflationary effect on product prices. In terms of marginal analysis, the subsidy per unit of output is no longer large enough to

into the analysis and a new tax which absorbed only loanable funds were assumed, leaving consumption funds initially unaltered, the "income effect" described by Rolph would cause a rise in consumer demand for X and Y unless the community's marginal propensity to consume were zero. For simplicity's sake I shall continue to assume throughout this comment that saving and investment are nil and that taxes absorb only consumption funds.

[6] A constant tax revenue would not offset the subsidy under all conditions, since *ad valorem* subsidy payments vary with the prices of X and Y.

offset completely the reduction in the prices of X and Y forced by the reduction in disposable incomes, so that marginal revenue becomes less than marginal cost. As a result, firms reduce their demands for resource services; incomes of owners of resources fall; the demand curves for X and Y are shifted downward again; and so on. What brings this deflationary spiral to a halt is the fact that, as income falls, income tax receipts also fall. When they have fallen by an amount equal to the difference between the amount brought in by the new tax and the amount paid out in subsidies, the budget is once more in balance and equilibrium is reached.

3. Suppose another situation: the subsidy is accompanied by a tax, independent of income, sufficient to defray *half* the expense of the subsidy; also, income tax rates are such that half of increments to income are taxed away. In this situation equilibrium is reached when incomes rise sufficiently to raise income tax receipts by an amount sufficient to defray the other half of the expense of the subsidy. Incomes must rise by the full amount of the subsidy. The eventual position of equilibrium is the same as that described by Rolph. But if we regard this final outcome as reached by a succession of steps, and if demand is assumed to be a function of actually received income rather than anticipated income, the initial effect is different. The new tax shifts the demand curves for X and Y, and their prices fall by half the amount of the subsidy per unit. Only after the other half of the subsidy is passed on to owners of resources in the form of higher explicit and implicit prices of resource services does a partially offsetting upward influence on the demand for X and Y come into play, raising their prices and firms' marginal revenues. The higher product prices now raise firms' demands for resource services further, causing incomes to rise further, and so on, until product prices are restored to their original levels.

4. Suppose all taxes are direct taxes independent of income; suppose uniform excise subsidies of the specific type are imposed on X and Y; and suppose a new tax is imposed which brings in receipts exactly equal to the subsidy payments. (Alternatively, we could suppose an *ad valorem* subsidy and a continually adjusted tax, as in [1] above.) Under these conditions the government budget remains in balance regardless of changes in prices or incomes. Numerous equilibrium positions are equally possible: (1) in which incomes are increased by the amount of the subsidies, while product prices remain unchanged, as in Rolph's model; (2) in which product prices are decreased by the full amount of the unit subsidy, while incomes remain unchanged; (3) in which some part of the subsidy is shifted to consumers, the rest to owners of resources. The outcome is determinate only if additional assumptions are made, either (a) specifying consumer behavior when real cash balances change, and specifying whether or not the money supply remains constant, or, if consumer behavior is unaffected by changes in the real value of liquid assets, (b) specifying relative lags in responses to changes, as, for example, in adjustment of income payments received by owners of firms to changes in profits, and in adjustment of prices of resource services to situations in which marginal revenue and marginal cost are unequal. If the new tax reduces the demand for X and Y by the full amount of the tax before the income effect

of the offsetting subsidy has had a chance to negate the effect of the tax, the whole subsidy will be shifted to consumers. But if the initial income effect of the subsidy acts first, the model will conform to Rolph's analysis. If both influences take effect gradually, some portion of the subsidy will be shifted to consumers. If we assume an *ad valorem* subsidy and a constant addition to tax revenue, the outcome is determinate without additional assumptions; equilibrium is reached at those prices for X and Y at which the subsidy brings in an amount equal to the tax rate.

The above comments are equally pertinent to the study of the effects of differential or partial subsidies. If, in Rolph's model in which a subsidy is imposed on X and not on Y, the market price of X is unchanged and "there is no compensating fall in the demand for Y," it must be that no offsetting tax has been imposed (or, at least, taken effect), so that, for the time being, deficit financing bolsters demand and pushes up incomes.

Two broad conclusions seem called for:

1. The effects of an economy-wide tax or subsidy cannot be studied satisfactorily if analysis is restricted to partial equilibrium analysis. The question whether incomes rise or prices fall throughout the economy is a macroeconomic one and its answer depends on the monetary and fiscal measures being employed.

2. In an economy which collects some part of its taxes in the form of income taxes, the effect of a universal excise tax or subsidy depends on the level of aggregate income (and also, in the case of an *ad valorem* tax or subsidy, on the level of product prices) at which government receipts and payments are in balance. Only at the budget-balancing level is equilibrium reached in an economy without saving or investment. An excise subsidy, therefore, increases the price of resource services (and thus raises the incomes of their owners) only if, and to the extent that, the existing level of aggregate income is below the equilibrium level.

LAWRENCE ABBOTT*

A Theory of Excise Subsidies: Reply

Professor Abbott's criticisms are centered around his question, "Where does the government get the money with which to pay the subsidy?" (par. 4). Failure to deal with the implications of this question is the basis for his charge of my having engaged in implicit theorizing and, ironically, of partial analysis. I dealt briefly with the question in Section IV of the article under discussion but apparently with little success.

The issue raised by Abbott is an old and fundamental methodological one in fiscal theory. Can the effects of a particular public finance act be assigned to that act alone? Abbott wishes to ascribe to a subsidy the consequences of any tax or borrowing device deemed to be occasioned by the subsidy. If he is correct, attempts to formulate a separate theory of the effects of particular taxes or subsidies must be abandoned. The "effect of a subsidy" becomes the effects of at least two fiscal acts: the payment of the sub-

sidy and the levy of some tax or other financing device. Since the possible financing devices accompanying a subsidy are innumerable, one must be content to list mere possibilities—as Abbott does in his cases numbered one through four. His "models" could be multiplied indefinitely. Logically, he might have concluded that a separate theory of taxes or of subsidies has no meaning: there are only effects of various tax-subsidy, loan-subsidy, tax-expenditure, or loan-expenditure measures. The position he adopts is somewhat similar to that taken by De Viti de Marco and Duncan Black. My position is essentially that adopted by Edgeworth, Pigou, and Lerner.

I do not believe it to be self-evident that one should consider where the government gets the money to pay a subsidy in developing a theory of subsidies or how it spends tax proceeds in developing a theory of taxes. In practice, there is no conceivable way of finding out which taxes "pay for" subsidies to farmers or to veterans. Likewise no one can say which tax receipts or bond sales pay for the Air Force. Such questions have no conceivable answers and therefore have no meaning. The investigator who insists upon attempting to answer such questions must therefore be content to elucidate mere possibilities. By contrast, a study of subsidies or of taxes which attempts to reveal the effects of each type of fiscal act separately does permit the development of theories which apply to any possibility.

The procedure adopted in the article in question is soberly orthodox. Each class of fiscal acts is analyzed under *ceteris paribus* conditions; the effects of subsidies are ascribed to subsidies, of taxes to taxes, and of debt operations to debt operations. Contrary to Abbott's views, such a method does not preclude global analysis of government finance; it is by this route that all effects of fiscal actions may be discovered. Let us not make the mistake of supposing that there is something left out of account, such as deficits or surpluses, by this procedure. These have no effects independently of the effects of government expenditures, transfer payments, taxes, or debt operations. Deficits or surpluses are arithmetical computations, not fiscal acts, and are knowable only after the fact. Money creation by government has no causal significance either. The effects discussed under this guise are the joint results of the positive fiscal acts adopted—loans, taxes, subsidies, and expenditures. Abbott's remarks (as well as much textbook comment) appear to need some revision on this point.

Abbott's cases are too detailed to be discussed point by point but certain observations about them may be pertinent. Throughout he treats consumption as a function of income although net investment is assumed to be zero. Since, however, C equals Y under such assumptions, C cannot be a function of Y. The concept of a propensity to consume under such assumptions is inappropriate. Consequently, Abbott's aggregative system is left ambiguous.[1]

[1] Abbott employs a framework of zero net investment which he regards as also implied in my analysis by my assumption of full employment of resources (see his fn. 3). No such implication was intended in the article nor does full employment appear to imply any particular figure, including zero, for net investment. Gross investment means the money value of new real assets produced during the period and, as such, is a classification of output. Net investment is this sum minus the value of existing resources used up. Full

His cases suggest that the possibilities are so numerous and that shifting may occur in so many different ways that any generalized theories are inherently overstatements. Partly the problem may be that subsidies and taxes are viewed as shiftable even in cases where it is already assumed that the information concerning the amounts involved and the identity of those who pay the tax or receive the subsidy are known. Thus Abbott writes: "If the new tax [a flat-sum tax] reduces the demand for X and Y by the full amount of the tax before the income effect of the offsetting subsidy has had a chance to negate the effect of the tax, the whole subsidy will be shifted to consumers" (p. 894). Although specific excise subsidies are being assumed in this case, the argument could equally well be applied to flat-sum subsidies. By the reference to the income-effect of the subsidy (the increase in the incomes of those obtaining government money), the identity of those subsidized is treated as established. The "shifting" indicated occurs because those who are subsidized happen not to increase their expenditures as much as those subject to the flat-sum tax reduce their expenditures. But shifting of either taxes or subsidies cannot occur in this way. Tax and subsidy theory offers an explanation of how such fiscal devices redistribute income between the government and private groups and how they change relative distribution of income among private groups. Thus, for example, it may not be validly argued that a highly progressive income tax is shifted merely because the rich curtail their expenditures and thereby indirectly increase the real income of the poor. Such a proposition already presupposes that it is a known and definite fact that the tax rests upon the rich and as a result of that fact they curtail their expenditures as compared to the alternative of no tax. Accordingly, neither the tax nor the subsidy is shifted to consumers because people choose for some or no reason to spend less money from one period to the next and prices adjust downward from previous levels.

As to Abbott's two conclusions, I agree with the first without, however, agreeing with the apparent intended implication of the first sentence. The partial analysis technique in the commonly accepted meaning of that phrase—one-commodity-at-a-time approach—was definitely not the method used in the article in question.

As to his second conclusion, I see no advantage and many disadvantages in restricting one's analysis of subsidies or taxes to the special case of a balanced budget, if this is the intent of his penultimate sentence. In practice, budgets are not typically balanced. But in any event, Abbott's concluding sentence seems inappropriate. Subsidies paid by the government to private groups do something to them, regardless of whether aggregate income is above or below its "equilibrium level." This "something" is a positive element in the income of those initially subsidized. They may not be able to retain all of the subsidy because the subsidy formula may induce a type of behavior which shifts the

employment of existing resources can and does exist with a substantial rate of net investment. The shifting argument as developed in the original paper can be applied to an economy in which all output consists of new resources (zero consumption). Here and elsewhere I detect in Abbott's thinking an inclination to regard stationary conditions as the proper setting for fiscal analysis—a view which seems to me to be needlessly limiting.

income to other groups. If the subsidy is of the excise type and happens to be general and uniform, this income shifting occurs by increasing the prices of hired resources under full employment conditions and of increasing their incomes via greater employment under less than full employment conditions. If the subsidy is not general, there is in addition a reallocation of resources in favor of those products heavily subsidized relatively to others. These conclusions hold regardless of what other financial devices the government may simultaneously employ, if any, including excise taxes. A system of subsidies may of course be offset by a system of taxes (as noted in Section IV of the article), but before such a statement can make any sense, one must know what effects of what fiscal devices are being offset.

Abbott's remarks, being directed almost entirely to the case of a general and uniform subsidy of all products, may misdirect attention from the main possible applications of the theory. In practice, governments are selective as to what products they subsidize as well as to what products they tax. Theories are needed to provide guidance to investigations of the effects of subsidizing housing, subway service, air transport, postal services, exports, and various food items. I agree wholeheartedly with the tone of Abbott's statements that partial analysis which does no more than glue attention on the particular industry subsidized—a common practice—may gravely distort research in these areas. Industries draw on a common pool of resources and are inherently interrelated. The implications of the extreme case of uniform and general excise subsidies are instructive as to the need for avoiding the error of regarding a subsidy to private enterprise or a loss on government enterprise in isolation, and in particular for avoiding the implication that subsidies necessarily "benefit" the buying public. In a competitive world, shifting of subsidies to consumers is not a real possibility.

Elasticities, Cross-Elasticities, and Market Relationships: Comment

The value-theory literature of the nineteen-thirties in general, several revealing comments by Kaldor in particular, and especially Triffin's pioneering work in 1940 suggested to economists that it should be possible to classify market relations between sellers by cross-elasticities of demand alone. In an interesting recent article Professor Bishop called attention to certain difficulties which develop in connection with cross-elasticity classifications.[1] He suggested that we should turn to a different classificatory principle, using the ratio of own elasticity to cross-elasticity, as well as the own elasticity (*i.e.*, demand-elasticity with respect to the commodity's own price) separately. The present note expresses views summarized by the following propositions:

1. The difficulties which Bishop discusses do not legitimately arise if we are

[1] Robert L. Bishop, "Elasticities, Cross-Elasticities and Market Relationships," *Am. Econ. Rev.*, Dec., 1952, XLII, 779-803. A very useful bibliography, including references to Kaldor's and Triffin's work, is found in footnotes 1 through 3, p. 779.

concerned with the problem of classifying the ideal market structures of economic theory. Bishop seems to be unaware of this; at any rate he does not explain that his difficulties develop on a different level of analysis. In the subsequent pages I shall describe a simple system, based on cross-elasticities of demand alone, which seems satisfactory for the classification of the ideal structures. In my opinion it is an essential property of our concepts of market relations that they can be so defined.

2. Bishop's difficulties do legitimately arise on a lower level of abstraction the nature of which remains unexplained in his article. These difficulties deserve attention if we are concerned with developing criteria for deciding whether a real market relation does or does not satisfy some ideal relation "reasonably well." This is a different task from that described under (1). To this task my suggested classification of ideal structures is unsuited.

3. However, when concerned with the second task, we may apply a simple adjustment to the basic classification here suggested, without bringing in new concepts other than that of limited sensitivity. The resulting adjusted cross-elasticity classification is suitable to the second task. It is simpler than that suggested by Bishop and it avoids considerable logical difficulties which would be created by the use of Bishop's classificatory principles.

I. *Classification of Ideal Market Structures*

A purely competitive market structure is an ideal structure (model) in which a group of firms is treated as if it were producing a literally homogeneous product, the output of the group is treated as if it were infinitely greater than the individual output of a firm, and measuring rods are supposed to be infinitely fine with the result that reactions to changes in variables are viewed as continuous. The last of these working hypotheses (idealizations) implies that our analysis proceeds as if it were possible to observe the consequences of so-called infinitesimal price changes, that is, the *limit* of the ratio of the effect of a price change to the price change itself, when the magnitude of the price change is made to approach zero. If each firm actually could observe the consequences of infinitesimal price and quantity impacts, then the number of producers would have to be infinite in order to rule out oligopolistic interdependence. Concern with a limiting situation where numbers are treated as infinite and use of the infinite-sensitivity assumption are interrelated. The infinite-sensitivity assumption in turn is required for performing operations along continuous functions.

In its ideal form the concept of monopolistic competition in the large group incorporates the same idealizations, with the significant exception that the idealization pertaining to product-homogeneity is omitted. The members of the group, whose number is treated as infinite, are located not in a point but in a conveniently delimited region of the substitutional universe. The ideal form of pure or undifferentiated oligopoly differs from that of pure competition in that the group-output is treated as finite in relation to the firm-output. Therefore an hypothetical individual demand curve based on given other prices would shift whenever a firm moved along it: The rivals would feel the consequences of such a move and they would change their prices. In the ideal

form of differentiated oligopoly, or monopolistic competition in the small group, only one of the idealizations is retained, namely that concerning the continuity of reactions to infinitely small impacts. Numbers are not treated as infinite and the product is not treated as homogeneous. As long as, for methodological reasons, we postulate sensitivity to infinitesimal impacts, treating numbers as finite means placing a structure in the category of oligopolies. The effect of oligopolistic interdependence on market results may gradually diminish as the number of producers rises, even though their number stays finite; but a theory of *oligopoly* is required for proving this, if sensitivity to infinitesimal impacts is postulated.

No one ever believed that real market structures could be found which would possess the characteristics of the ideal ones, just as no one drawing, for example, a continuous Lorenz curve for an income-distribution, ever believed that the population of, say, a city, was perfectly divisible (*i.e.*, really consisted of an infinite number of the units arrayed along the abscissa). The real existence of a perfectly divisible population is as "unimaginable," as the real existence of an infinite number of firms in a point or in a finite region of the substitutional universe.[2] Sensitivity to infinitely small impacts also is unimaginable. But this in itself is irrelevant. In all sciences benefit can sometimes be derived from analysis in terms of models based on limiting assumptions of this sort. The results of such analysis frequently prove to be simple and good approximations to reality. Economists have of course been much less successful than natural scientists in their attempts to derive empirically significant conclusions from their ideal models. But, while in economics we usually cannot apply the results of pure analysis without making disturbingly large allowances for the imperfections of the real world, it remains a fact that our basic theories were established in terms of idealized models, and that the practical concept of market relations must be connected with ideal concepts, which can serve as a basis for generalized theoretical analysis.

I now turn to my first objective. This is the classification of ideal market structures, that is to say, of models in terms of which fundamental theories were developed rather than of structures "existing" in the real world. The classification can be undertaken with the aid of cross-elasticities of demand alone, and is summarized in Table I. Throughout this note, symmetry of market relations will be assumed. In other words firm-labels may be interchanged.

In the table E_{ij}^{U} stands for the cross-elasticity (logarithmic partial derivative) of the demand for the product of firm i with respect to the price at which firm j is willing to sell, when the price change is a price-increase. The concept will be called upward cross-elasticity. E_{ij}^{D} stands for downward cross-elasticity analogously defined. The initial situation must of course be conceived of as one in which both firms are actually selling.

The following explanatory comments should be added.

1. In pure competition the downward cross-elasticity of demand is infinite because if, *ceteris paribus*, firm j reduces its asking price infinitesimally, then

[2] The analogy should not lead us to overlook the fact that the substitutional universe has many more dimensions than natural space.

no other firm can sell at all. Such an experiment would of course destroy the initial market structure; firm j would displace all other firms, which produce the commodity in question. But this is no objection, since we are interested in identifying market structures not in conserving them. The cross-elasticity of demand expresses the effect on the demand for the product of i of a postulated price-change by j during the time-interval in which j is willing to sell at the changed price. While j is willing to sell cheaper, i can sell nothing at the original price. It is true that we are here concerned with merely *pure* (not necessarily perfect) competition, and that certain frictions are compatible with competition that is pure but not perfect. Perfect mobility is not postulated. But we are still dealing with an analytical idealization which would become undefinable by cross-elasticity, own elasticity, or any other formal criterion if we allowed the same commodity to be sold simultaneously at

TABLE I.—CLASSIFICATION OF MARKET RELATIONS

(Suggested for Definition of Ideal Structures by Consequences of Infinitesimal Price Changes)

Relationship between Firms i and j	Upward Cross-Elasticity E_{ij}^{U}	Downward Cross-Elasticity E_{ij}^{D}
Belong in same pure oligopoly	∞	∞
Belong in same differentiated oligopoly	Finite positive	Finite positive
Belong in same purely competitive group	0	∞
Belong either in same monopolistically competitive large group or not in same "group" of any conventional description. (Answer depends on group-to-firm cross-elasticity criterion, defined on p. 903.)	0	0

different prices. This would mean that a differentiated product could not be formally distinguished from one that is undifferentiated. Even in merely pure competition we have to insist on the inability of a producer to sell at a given price while another producer is willing to sell at a lower one. Hence downward cross-elasticity is infinite.[3]

On the other hand, upward cross-elasticity is zero in pure competition. If firm j raises its asking price infinitesimally, it faces zero-demand, and thus it removes itself from the market, but the sales gains which result from this

[3] If "pure" competition were interpreted as sufficiently imperfect to allow for the simultaneous sale at different prices of the identical commodity, then only perfect competition would be formally definable. The definition of perfect competition with its minimum long-run cost and zero-profit implications requires cost concepts, mobility-immobility concepts and certainty-uncertainty concepts in addition to demand concepts. Normally we conceive of pure competition as possibly imperfect but not so imperfect as to allow for the coexistence of more than one price for a homogeneous commodity. Only on this interpretation does pure competition become formally definable at all and in this case it can be defined by cross-elasticities of demand alone.

for others are distributed among producers whose number is treated as if it were infinite. In any undifferentiated market, atomistic or oligopolistic, the demand for the output of the individual firm i results from a random distribution of the as yet unsatisfied demand for the commodity as a whole at a given price; hence in an ideal undifferentiated *and atomistic* market the removal of j does not change the demand for the output of any individual rival.

2. If both upward and downward cross-elasticity are zero, this means that the two firms belong in the same monopolistically competitive large group, provided that they are viewed as belonging in one and the same group at all. In the monopolistically competitive large group the upward cross-elasticity is zero because the consequences of a reduction in the sales of an individual firm —say, of j—are distributed among firms the number of which is treated as if it were infinite. Among these there may exist a finite number of oligopolists but there must exist an infinite number of firms, such as i, for which the demand-increment is zero. The downward cross-elasticity also is zero because when the degree of price-reduction by j is made to approach zero, the sales-increase of j is a finite multiple of this small price-reduction and hence the reduction of demand for i becomes zero. $E_{ij}^U = E_{ij}^D = 0$ is a necessary condition of the ideal form of large-group monopolistic competition with which Chamberlin seems to be concerned in his as yet unpublished essay on market classification.[4] The ideal form implies an infinite number of producers and hence zero cross-elasticities. In *The Theory of Monopolistic Competition* Chamberlin says that for some purposes it is legitimate to treat the number of producers in atomistic structures as infinite but his detailed analysis there relates to the "real" (practical) structures to which we shall turn in Section II.

$E_{ij}^U = E_{ij}^D = 0$ is a necessary but not a sufficient condition of the ideal form of large-group monopolistic competition. This condition is satisfied also between two firms which are viewed as not belonging in the same group. An

[4] Bishop, who gives an account of this essay (conference paper) accuses Chamberlin of "odd perversity" for maintaining that while cross-elasticity may be infinite in the undifferentiated large group, it falls to zero with the least differentiation. But Chamberlin is quite right. The difference between homogeneity and the least differentiation is that in the event of homogeneity the price-reducing firm increases its sales in infinite proportion of the firm-output (and indeed displaces all other firms) regardless of how small the price-reduction becomes, while in the event of the least differentiation the sales-increment of the price-reducing firm can be made smaller than *any* finite magnitude provided that the price reduction becomes small enough. The proposition implies of course continuous demand curves.

This is not to deny the logical possibility of starting with, say, two differentiated producers and of increasing the number of firms in such a way that the cross-elasticities of demand should stay unchanged or should rise. But it is surely possible to increase the number of firms in such a way that the cross-elasticities should be falling with the result that the process tends toward a situation where the own elasticity stays finite and the sales-loss or gain of a firm in the event of unilateral price changes becomes distributed among an ever increasing number of other firms. In these circumstances, the fall in the cross-elasticity reflects the circumstance that, as the variety of products increases, a decreasing proportion of the customers of each firm can be tempted easily to shift to and from any one (increasingly specialized) rival. The own elasticity need not fall and it may conceivably rise, because it measures the joint temptation to shift to and from a great many rival specialities. This is how we arrive at the monopolistically competitive large group.

isolated monopoly satisfies this condition with all other firms.[5] The two firms belong in the identical monopolistically competitive large group only if, in addition to $E_{ij}^U = E_{ij}^D = 0$, another condition also is satisfied. A convenient way of expressing the further condition is to require that each of two group-to-firm cross-elasticities should exceed a critical value. The two group-to-firm cross-elasticities measure the demand-effect on i and on j, respectively, of a price change undertaken by all members of a group of firms[6] satisfying the following indivisibility requirement: the group must not be divisible into two subsets in such a way that one subset alone would show the required cross-elasticity in relation to i but not to j, and the other alone would show the required cross-elasticity in relation to j but not to i.[7]

A decision of analytical convenience must be made concerning the required or critical value of the group-to-firm cross elasticities. Problems of monopolistic competition are encountered as soon as each of the two group-to-firm cross-elasticities just described exceeds zero. For some purposes it is therefore possible to select zero as the critical value which must be exceeded. But frequently we wish to direct our analysis to an ideal group for which the value of the cross-elasticities in question is reasonably high, *i.e.*, to a fairly "close" group. This is because frequently we wish to construct the ideal equivalent of a real group which shows monopolistically competitive behavior in a significant measure, not just weakly.

3. The remaining definitional propositions of Table I seem self-explanatory.[8] The reader will notice that in this system a firm may very well be viewed as belonging in one group with some firm or firms, and in another group with others. We should add that extension of the classificatory system to symmetrical buyer-buyer relations,[9] and to asymmetrical relations, either between sellers or between buyers, would cause no difficulty. Nor would the extension of the system to complementary relations raise fundamentally different

[5] The ideal form of isolated monopoly may be defined as a firm i which satisfies the symmetrical zero-cross-elasticity condition with *all* other individual firms in the economy and can be paired with no other firm in such a way that both would satisfy the condition of sufficient group-to-firm cross-elasticity which will presently be described.

[6] In the ideal world this group must be treated as consisting of an infinite number of firms.

[7] This indivisibility requirement excludes establishing high group-to-firm cross-elasticities by lumping together all moving picture theatres and all stationery stores into one aggregate and by setting a group so constituted against a pair of firms consisting of a stationery store and a theatre. Such a group would satisfy the indivisibility requirement only for a very low group-to-firm cross-elasticity, corresponding to the relationship between the group of stationery stores and a moving picture theatre or the group of theatres and a stationery store.

[8] In differentiated oligopoly both the upward and the downward cross-elasticities are finite. As the price change by j approaches zero, the demand-effect on i continues to bear a finite proportion to the price-change. In pure oligopoly the downward cross-elasticity is infinite for the same reason as that which produces infinite downward cross-elasticity in pure competition; and the upward cross-elasticity is infinite because an infinitesimal price-increase by j removes j from the market and hence it increases the demand for the output of each rival in a finite proportion.

[9] With the aid of cross-elasticities of supply.

problems.[10] However, the system here presented can be employed only as a point of departure for the analysis of essential questions, such as those relating to the emergence and the survival of market structures and the behavior of firms under alternative market conditions. The analysis of these questions requires cost-concepts, mobility-rigidity concepts and certainty-uncertainty concepts as well as demand concepts. Furthermore, analysis that covers the whole network of economic activity requires the use of group-to-group as well as firm-to-firm and group-to-firm cross-elasticities.[11]

II. *Criteria of the "Practical Belonging" of Real Market Relations in Various Categories*

On the level of abstraction on which the analysis of Section I was conducted, the classification of Table I is satisfactory and hence Bishop's misgivings concerning cross-elasticity classification seem unjustified. We must interpret Bishop as being concerned with problems arising on a lower level of abstraction where he legitimately encounters the difficulties which he discusses. What imperfections of the real world do we have to take into account to arrive at this level of abstraction?

In the real world measuring rods are crude and successive reactions are forthcoming merely to finite changes in variables when these changes exceed certain threshold values. The limited sensitivity of measuring rods is the reason why a group may be *practically* nonoligopolistic even though the number of firms in it is finite.[12] A group is *practically* nonoligopolistic ("large") if the individual firm is an unnoticeable unit to its rivals; and the product is *practically* homogeneous if certain individual price-changes would completely eliminate the demand for the product of existing firms. In the practical universe we must "test" for these market characteristics by the consequences of *ad hoc* selected finite price-changes.

[10] Complementarity will express itself in negative cross-elaticties. Here it is not desirable to eliminate income effects because the nature of market relations is influenced by them.

[11] The system developed in my *Competition Among the Few* (New York, 1949), pp. 50-54, is much more complete in all these respects. The principles underlying my earlier classification are identical with these here employed but the earlier classification would be unnecessarily complex for the present purpose.

[12] If an oligopoly theory such as that of Cournot were acceptable, then a market structure could be "practically nonoligopolistic" in another sense, even on the assumption of infinite sensitivity. For example, in Cournot's theory, a group of 99 firms would produce 99 per cent of the competitive output, and hence the size of the group-output, and generally the market results, would be practically nonoligopolistic (practically purely competitive) even though the behavior of the group would be fundamentally oliogopolistic. But of course we do not wish to commit ourselves in advance to any such specific theory of oligopoly. Moreover, we want to take account of the fact that when in the real world a large group of producers is said to behave "atomistically," this is so because the limited sensitivity of firms makes them unaware of each other's individual influence, not because fundamentally oligopolistic awareness makes them produce results which in this particular case we may not wish to distinguish from the atomistic-competitive ones. If we find oligopolistic awareness in a real group, we want to place the group practically in the category of oligopolies and then turn to the question of what market results may be expected in the given oligopolistic circumstances.

Can we test in the practical universe with the aid of Table I? If we wanted to use the table for this purpose we would of course have to interpret the cross-elasticities of the table as incremental ratios, with conveniently chosen *finite* proportionate price changes in the denominator and the corresponding proportionate quantity changes in the numerator; and we would have to enter subjectively unnoticed ("negligible") quantities as zeros.

Table I is inadequate for testing by the consequences of finite price changes in the practical universe. The valid content of Bishop's analysis can be translated into our terminology by stating that Table I with finite price changes is not a reliable instrument when it comes to testing a real market. Bishop's illustrations of his problem never strictly observe the rules of the ideal universe, while, at least in most respects, they do conform to the rules of the practical universe which we are now considering. In his analytical operations the number of firms in large groups is always treated as finite, and what he calls a "small" price-reduction (a "shading" of the price) may result in a conceivably "enormous" increase in sales (*op. cit.*, p. 788). These are not infinitesimal price changes.

If Table I were used for testing real market structures with finite price changes, then two difficulties would arise.

A. The first difficulty gives rise to what appears to be Bishop's main problem. Table I tells us that a finite value for downward cross-elasticity is in itself conclusive evidence of an oligopolistic relationship. In large-group monopolistic competition downward cross-elasticity would have to be zero. But if we think in terms of limited sensitivity and of discontinuous reactions to successive finite changes in variables, then this ceases to be true. An hypothetical reduction of the price of firm j by, say, 10 per cent could result in growth of the firm from a subjectively unnoticed size to a size which is clearly noticeable to the individual rival. Downward cross-elasticity could be finite. Yet in such circumstances we would not wish to identify the new existing relationship as oligopolistic, any more than we wish to call a purely competitive structure monopolistic merely because a price-reducing firm could monopolize the market if the others kept their prices constant. Bishop attributes considerable importance to this difficulty. In his illustrations an atomistic differentiated structure may show higher cross-elasticity than an oligopolistic structure, provided that in the atomistic structure the own elasticity of the price-reducing firm is high enough. However, Bishop does not make it clear that this difficulty is a consequence of the finiteness of price changes by which, in a world of limited sensitivity and finite numbers, an initially unnoticed price-reducing firm is "made to change" to a noticeable one. The difficulty would not arise in a world of unlimited sensitivity because there the finiteness of cross-elasticity, as discovered by the test of an infinitesimal price change, would dependably disclose oligopolistic interdependence in a differentiated group. The difficulty would be spurious if in a world of limited sensitivity we were trying to test with infinitesimal price changes and thus were attributing to the system a sensitivity which it does not possess. A legitimate difficulty develops only if in a world of limited sensitivity we are testing with finite price-reductions, and in this case the

difficulty springs from the fact that a finite price-reduction may raise a variable—the sales of a rival—beyond a threshold value. This is how we should interpret Bishop's problem. At the same time Bishop does not make it clear that, taking limited sensitivity and finite price changes for granted, the difficulty can be avoided by using upward rather than downward cross-elasticity for oligopoly tests. If firm j, by reducing its sales or by removing itself from the market, could exert a noticeable influence on a rival, then we do wish to consider this relation oligopolistic. It would of course be very arbitrary to use the numerical value of the upward cross-elasticity, or any other figure, as a unique index of the degree of oligopolistic intensity, but the value of this cross-elasticity does dependably indicate whether, at the time of testing, oligopoly (noticeable individual firm-size) does or does not exist. The conclusion so far is that *a table which can be used for testing real markets should differ from Table I in that it should always require testing for oligopoly by upward cross-elasticity.* For "nonoligopolistic" relations and only for these will the value of this cross-elasticity be zero (*i.e.*, an unnoticeable quantity-change divided by a finite and noticeable[13] price-change).

B. We now turn to the second difficulty in connection with use of Table I for real testing. Bishop does not discuss this second complication, although some passages of his analysis may show awareness of it.

Table I tells us that a finite value for upward cross-elasticity in itself discloses the existence of product-differentiation in oligopoly. This is true only when we assume infinitesimal price changes. With finite price changes, which are necessarily implied in any consistent interpretation of the Bishop problem, a finite value for upward cross-elasticity is inconclusive. The value of this magnitude, interpreted as an incremental ratio rather than a limit, will be finite (a ratio of two finite magnitudes) even if the product is homogeneous, provided that the group is oligopolistic. If firm j raises its price by 10 per cent and this leads to a 20 per cent increase in the sales of firm i, we do not know whether this is because j is a comparatively small oligopolist in an undifferentiated market (who completely removed himself from the market), or a comparatively large oligopolist in a differentiated market (who merely reduced his sales). However, the same difficulty does not develop if we test for product-differentiation by downward instead of upward cross-elasticity. Assume that firm j reduces its price by a conveniently selected critical margin, satisfying all the demand which it faces at that price and that this completely removes firm i from the market. In this case and only in this case are we willing to classify the product as practically homogeneous.[14] If by this cri-

[13] The quantity change for i is unnoticeable; the price-change by j has a noticeable effect on j itself.

[14] An unimportant complication may here be mentioned. Firm j may in the initial position be selling a differentiated product at such a low price, in relation to that of i, that a further small price-reduction completely removes firm i from the market instead of reducing its sales. In this case our criterion wrongly indicates product-homogeneity. Such pricing by i at precisely the upper border of the zone of coexistence, and by j at precisely the lower border, can be disregarded. Circumventing this complication would require making practical homogeneity dependent on the size of initially observable price-differentials. But this has the disadvantage of calling for an arbitrary decision as to what prices are precisely "equal"

terion the product *is* homogeneous, then we may consider the downward cross-elasticity infinite because the sales reduction which i suffers bears an infinite proportion to the zero-sales with which it ends the experiment.[15] The conclusion is that *a table which can be used for testing real markets should differ from Table I in that it should always require testing for product-differentiation by downward cross-elasticity.* For homogeneous products the value of this will be infinite, for differentiated ones finite. This is the adjustment of procedure for which the second difficulty calls.

Our task is to adjust Table I to the practical universe, and thus to avoid having to turn to different principles for the testing of real relations. The essential step in the adjustment is to omit (or make less specific[16]) some of the information contained in Table I and thus to derive Table II.

TABLE II.—CLASSIFICATION OF MARKET RELATIONS BY LESS SPECIFIC DESCRIPTION OF FINDINGS ENTERED IN TABLE I

(Suggested for Testing Real Market Relations by Consequences of Finite Price Changes. Elasticities then Become Incremental Ratios, not Limits in the Sense of Calculus)

Relationship between firms i and j	Upward Cross-Elasticity E_{ij}^U	Downward Cross-Elasticity E_{ij}^D
Belong in same pure oligopoly	Positive	∞
Belong in same differentiated oligopoly	Positive	Not Infinite
Belong in same purely competitive group	0	∞
Belong either in same monopolistically competitive large group or not in same "group" of any conventional description. (Answer depends on group-to-firm cross-elasticity criterion, defined on p. 903.)	0	Not Infinite

If we could test by infinitesimal price changes and could possess the data required for placing a structure in a box of Table I, we would always have to place the structure in the identically described box of Table II, simply by listing our data in less detail (less "sensitively"). An ideal structure possessing the characteristics of a category in Table II would also possess the *additional* characteristics of the same category in Table I. The ideal relations stay defined by the conditions of Table I.

However, if Table II is used for the testing of real markets by *ad hoc* selected finite price changes, then it performs a useful analytical function. The two difficulties which were discussed in the present section are avoided. According to Table II, oligopoly is diagnosed by the noticeability to rivals of

in a differentiated market. Quantity measures which would be common to all species of a genus may not be easily found.

[15] In the event of finite changes it is of course always arbitrary whether a proportionate change is computed in relation to the bigger or the smaller of two quantities. Here it is convenient to compute it in relation to the smaller.

[16] Less specific in the sense in which "positive" is less specific than "positive infinite."

a price *increase* undertaken by an individual firm, that is, by the non-zero value of upward cross-elasticity. Product-homogeneity is diagnosed by the complete removal from the market of all other members of the group, under the influence of a conveniently selected critical price *reduction* by a single firm. It is diagnosed by the infinite value of downward cross-elasticity.[17] In the ideal universe of Table I any combination of atomism-oligopoly with homogeneity-differentiation *could* be diagnosed by this same double test; but in the ideal universe some structures are recognizable in a simpler way by a single test, based either on upward or on downward cross-elasticities.

Table II describes reasonable criteria for the classification of real market relations. Tests of this sort can of course rarely be carried out by statistical analysis but it must be assumed that persons familiar with conditions in an industry are capable of making estimates which are helpful for answering the questions posed by Table II. These questions relate to the order of magnitude of firm-to-firm and group-to-firm cross-elasticities.

Using Table I, with infinitesimal price changes, for the definition of ideal market relations, and Table II, with *ad hoc* selected finite price changes, for the testing of real markets, has the advantages of linking our two universes of discourse by a well-defined procedure. By *practically* belonging in a specific category, according to Table II with finite price changes, the various structures satisfy some but not all conditions of *ideally* belonging in their respective categories. By comparing the two tables it is possible to indicate what imperfections we temporarily neglect if, in the first approximation, we treat "practical belonging" in a category as if it were "ideal belonging," thus gaining the advantages of operating along continuous functions. The decision concerning the magnitude of the price changes for testing must of course be made dependent on analytical objectives. In one instance we may be concerned with what happens in some specific range of changes, in another instance our concern may be with the effects of changes falling in a different range. Accordingly we may wish to place the same structure in different "practical" categories, to obtain a point of departure for the analysis of the consequences of firm and group behavior under given market conditions.

III. *Comparison with Bishop's Suggestions*

Testing by finite price changes, whether a moderately large group of somewhat insensitive producers behaves more-or-less like an ideal group in which the number of producers is treated as infinite, is of course a different task from that of defining a model in which the number *is* treated as infinite. The diffi-

[17] Practical belonging of i and j in large-group monopolistic competition requires not merely that the structure should fall in the last row of Table II but (by analogy to the ideal world of Table I) also that the condition of sufficient group-to-firm cross-elasticities should be satisfied. Here too problems of monopolistic competition develop in principle as soon as the "critical" cross-elasticities are greater than zero but frequently we will want to insist on a higher critical value.

A firm practically belongs in the category of isolated monopoly if with all other firms in the economy it belongs in the last row of Table II, and if it satisfies the condition of sufficient group-to-firm cross-elasticities in conjunction with no other firm.

culties to which Bishop has called attention are real and important, but only if we are concerned with testing market relations by finite price changes under conditions of insensitivity to the very small.

Instead of overcoming the difficulties by some procedure such as that developed in the preceding pages, that is, by allowances for limited sensitivity, Bishop turns to a very different classificatory principle. He defines an elasticity *ratio*, dividing the elasticity of demand with respect to the own price (E_{ii}) by the cross-elasticity of demand (E_{ij}), and he states that this ratio tends to rise with the number of firms in the group.[18] More precisely, in a differentiated structure a high ratio of E_{ii} to E_{ij} means that, from the point of view of firm i, firm j has a small "weight" or relative importance in the universe of all firms.[19] Having thus tested for atomism-oligopoly by what he calls a "numbers-equivalent" (namely by the elasticity ratio), he proceeds to testing for homogeneity-differentiation by the own elasticity taken separately. For example, in Bishop's terminology a sufficiently high elasticity ratio and a sufficiently high own elasticity mark "near-pure competition." Low elasticity ratio and high own elasticity mark "near-pure oligopoly."

It should be added that not only the own elasticity is influenced in a rather complex fashion by product-differentiation but the cross-elasticity and the elasticity ratio also are. The elasticity ratio is not a pure indicator of numbers (corrected for size-distribution), since the relative weight or importance of j for i, in the universe of all firms, depends on relative substitutional distances as well as on numbers and on size-distribution. This is not overlooked by Bishop and it is not in itself a shortcoming of the ratio. Numbers and size-distribution create merely a vague presumption as to the nature of a group. In the real world we cannot avoid facing the question of limited sensitivity and of threshold values. Interest attaches to numbers only because they are more readily ascertainable than elasticities. But Bishop's suggestion that the elasticity ratio be called a "numbers equivalent" may not be fortunate.

The distinctive feature of Bishop's classification is the use of the own elasticity, and particularly the elasticity ratio, in addition to cross-elasticity concepts. Bishop needs the distinction between upward and downward cross-elasticity, as we do, although he disregards this distinction except in a footnote dealing with a side issue.[20] In addition he uses the own elasticity and its ratio to cross-elasticity. This is the characteristic property of his system.

[18] A double-sized firm should be regarded as the equivalent of two unit-sized firms.

[19] The own elasticity expresses the effect on firm i of a price change undertaken by all other firms (because, neglecting the income effect, this is the same thing as the effect on firm i of a price change undertaken only by itself); and the cross-elasticity expresses the effect on firm i of a price change undertaken only by firm j. The elasticity ratio therefore is inversely related to the relative significance of j in the group of all firms, from the point of view of i.

[20] In some of the cases which Bishop discusses in detail the value of the upward cross-elasticity is very different from that of the downward cross-elasticity. If, for example, a small firm in a differentiated market grows to many times its initial size by finitely reducing its price, the downward cross-elasticity must be many times greater than the upward cross-elasticity. For the context in which Bishop mentions the distinction between the consequences of price-increases and of reductions, cf. *op. cit.* p. 793, footnote 24.

Bishop's additional concepts are not needed for classification. Indeed, use of the elasticity ratio destroys something that is carefully preserved in the simpler classification presented in this paper. For, in the classification here suggested, homogeneous competition and oligopoly remain definable in the same framework that also serves for the definition of differentiated large and small groups. This is true of the ideal as well as of the closely related practical universe. The concept of differentiation does not become logically divorced from the concept of homogeneity. In Bishop's system it does. Reliance on the elasticity ratio excludes the unity of treatment here preserved. Bishop is aware of the fact that the elasticity ratio assumes the meaningless value of infinity divided by infinity in pure competition as well as in pure oligopoly.[21] His "near-pure" structures are defined with the aid of a concept which gives meaningless results for the "pure" structures. Why invite this logical difficulty if the concepts causing it are unecessary additions to upward and downward cross-elasticity which alone are required for classification?

WILLIAM FELLNER*

[21] In pure competition this is true only if downward cross-elasticity is used for computing the elasticity ratio. But Bishop thinks in terms of downward cross-elasticity. For the undifferentiated structures the logic of the elasticity ratio breaks down because if the effect of a price change undertaken by a single rival is expressed by "infinite," then the relative importance of that rival cannot be measured by comparing this effect with that of a price change undertaken by all rivals.

Elasticities, Cross-Elasticities, and Market Relationships: Comment

The article by R. L. Bishop on "Elasticities, Cross-Elasticities, and Market Relationships" followed, and apparently received a strong orientation from, a prepublication copy of my own paper on "Measuring the Degree of Monopoly and Competition," presented at the Talloires meeting of the International Economic Association in September 1951. In one section of my paper Robert Triffin's classification of the problems of monopoly and competition in terms of cross-elasticities alone, and in particular his statement that the (price) "coefficient of interdependence measures the relative share of monopoly and competition in the situation of the seller"[1] were subjected to various criticisms. It was concluded that cross-elasticity is significant only as a measure of isolation and that "elasticity as well as cross-elasticity is needed to classify the problems of monopolistic competition"—needed specifically as a measure of heterogeneity. In spite of his sweeping criticisms, Bishop seems to agree with me as to the need for elasticity and has even less faith in cross-elasticity than I had retained.

When Bishop's article was published it seemed likely that the proceedings of the Talloires meeting would appear shortly, as indicated by his footnote (p. 779). Alas, a year has passed and they are still in press, but present indi-

[1] *Monopolistic Competition and General Equilibrium Theory* (Cambridge, Mass., 1940), pp. 131-32.

cations are that they will soon be available[2] and that the reader will no longer be obliged to pass judgment on my position without having read my own full development of it in its original context,[3] where its appearance at all is explained mainly by Triffin's having advanced (price) cross-elasticity as a *measure* of monopoly and competition (*cf.* the title of my paper).

One might say loosely that Bishop's major contribution to a satisfactory solution of this range of problems is a convincing demonstration of the complexity, even the treachery, of cross-elasticity as a measure of anything. More specifically, he shows that price cross-elasticity does not provide a clean-cut distinction between isolation and nonisolation: the effect on the sales of firm j of a price adjustment by firm i may be "negligible" even though the supposedly relevant cross-elasticity is high. The reason is that *however small* the relative change in j's sales, $\Delta q_j/q_j$, the relative change in i's price, $\Delta p_i/p_i$, may (owing to high elasticity of i's demand curve) be *still smaller*, thus making the cross-elasticity coefficient, $p_i \cdot \delta q_j/q_j \cdot \delta p_i$, large. This is a demonstration of importance and amounts to showing that cross-elasticities of zero are a sufficient but not necessary condition to isolation. It follows that nonzero cross-elasticities are a necessary but not sufficient condition of nonisolation.[4] Because of Bishop's analysis we must now recognize explicitly that there remain cases of nonzero cross-elasticities where the question of whether a seller is isolated or not must be settled by other criteria.

In recent years I have been concerned to bring into a single category the two concepts of an "isolated monopolist" and of a single seller in the "large-numbers-differentiated-product" case; and this is an important part of the background of the classification appearing at the end of my Talloires paper.[5] A monopolist who is isolated in the sense of being able to disregard the interdependence between his own market and those of others is described in *Monopolistic Competition* as so situated that "the effects of a change inaugurated by [him] are spread over such a large number of competitors that they are negligible for each.[6] Similarly, the "large group" case is characterized by the fact that "any adjustment of price or of 'product' by a single producer spreads its influence over so many of his competitors that the impact felt by any one is negligible and does not lead him to any readjustment of his own situation" (p. 83). It seems clear that these two concepts come to the same thing, and it is important to identify them for a number of reasons. One of the reasons is to make clear that ordinary, traditional (isolated) monopoly, now commonly known as "pure" monopoly, is not pure at all, but an integral part of the monopolistically competitive system.[7] Such a monopoly may in

[2] *Monopoly and Competition and their Regulation* (London, Macmillan and Co.).

[3] This implies no misrepresentation by Bishop.

[4] *Cf.* Bishop, *op. cit.*, p. 787.

[5] *Cf.* also "Monopolistic Competition Revisited," *Economica*, Nov. 1951, XVIII, 353.

[6] *The Theory of Monopolistic Competition*, 6th ed. (Cambridge, Mass., 1948), p. 74.

[7] Bishop speaks of my "*long-standing conviction* that there is no such thing as a 'pure monopoly' short of a simultaneous monopolizing of all economic goods" (p. 785, n. 10, italics mine). It is indeed a "conviction" of long standing, but the language seems strange in view of the fact that the concept of pure monopoly certainly came into modern eco-

fact be correctly regarded as a single firm in a "large group" of some appropriately broader category. Similarly, a single seller in a group free from oligopolistic influences appears to be isolated as truly as the traditional monopolist (and therefore in the now prevalent terminology would be a "pure" monopolist, which is absurd).

From these considerations comes a second reason why the identification in question is important, *viz.*, that isolation and nonoligopoly are thus revealed as the same thing. This is certainly not what Triffin says in his schema, where, among other things, "isolated selling" is clearly not a part of "heterogeneous competition."[8] Yet in using cross-elasticity coefficients to distinguish isolation from nonisolation, I have merely followed Triffin (and also general usage) in this particular matter. It is not clear to me whether Bishop regards isolation and nonoligopoly as the same thing; but it is clear that his criticism of my use of price cross-elasticity as a test for *oligopoly* is equally applicable to Triffin's use of it as a criterion for *isolation*: Triffin's coefficient may be significantly large consistent with the isolation of firm *i*.

For these and other reasons, the manner in which Bishop singles out my own analysis and classification for nothing short of total condemnation seems strange indeed. Even though criticised only in part, it is rejected *in toto* as "unsuccessful" (p. 794), and, again *in toto*, because it "breaks down completely" (p. 797). This disposition follows the setting up of an unqualified black-and-white contrast between Triffin and myself: "I have chosen Triffin and Chamberlin as the principal antagonists [sic]," he says, "because of the dramatic clarity of their differences" (p. 785, n. 11). The differences are indeed substantial, but in pressing his contrast to the limit, Bishop is obliged to minimize (for instance, as "temporary back-sliding," p. 788) or to ignore altogether Triffin's very substantial use of price cross-elasticity, both as a measure of monopoly and competition and in testing for oligopoly; and to give to Triffin's position a one-sided definiteness which it simply does not have. This procedure causes great confusion, not only in understanding and appraising the real position of each of us, but also (and more important) in understanding the fundamental issues of the problem. It is especially confusing when we look at Bishop's own classification and find that in the end it is Triffin's which has been completely rejected and that he follows me as against Triffin (without saying so) in taking "own" elasticity, not cross-elasticity, as the proper measure of heterogeneity (pp. 797-98 and table).

nomics (possibly the term itself was used earlier—I do not know) as a part of my own terminology (*cf. Monopolistic Competition*, pp. 63-64) and is now widely perverted to a completely different meaning, usually without even a reference to its original one. The matter is important because the definitions of the two *limiting* cases of pure monopoly and pure competition are necessarily a part of the interpretation one gives to the theory "intermediate" between them, so that to redefine one of them is disastrous.

[8] *Op. cit.*, p. 104. In my Talloires paper I had criticised Triffin's identification of "heterogeneous competition" with a "finite value" of cross-elasticity, pointing out that "the coefficient approaches zero, not only under 'isolated selling,' but also under heterogeneous competition with 'large numbers.'" Bishop seems to agree with this criticism, for he refers to "the fact that this cross-elasticity may be indefinitely small under differentiated competition" as "at least somewhat embarrassing for Triffin" (p. 786).

Does Bishop's criticism invalidate the use of price cross-elasticity coefficients to measure the influence of one firm upon another, and hence to indicate the presence or absence of oligopoly? Certainly it does not completely, for a coefficient of zero[9] is still a sure sign of isolation, even though we may have isolation without it. But it appears certain that its usefulness is diminished. As I have indicated above, we are limited now to saying that zero coefficients are sufficient but not necessary to isolation, and that nonzero coefficients are necessary but not sufficient to nonisolation. The problem remains of distinguishing which of the cases with nonzero coefficients are isolated and which are not.[10]

After all, it is not surprising that this intermediate area should exist.[11] Tabular arrangements of coefficients may have their limited usefulness, but they also run the danger of making the problem look deceptively precise. I am bound to say that I still find unobjectionable my own statement of twenty years ago, as a description of isolation. It was quoted earlier, but let me repeat it: "that any adjustment of price or of 'product' [or of selling outlay] by a single producer spreads its influence over so many of his competitors that the impact felt by any one is negligible and does not lead him to any readjustment of his own situation."[12] It should be noted that zero cross-elasticities, though sufficient, are not necessary to isolation in this sense; and also that in the vexed case of pure competition, however one may rule as to the value of the cross-elasticity coefficient, a single seller is isolated in the sense described.

Recognition that the line of separation between isolation and nonisolation is not precise in terms of some particular cross-elasticity coefficient seems to me to affect in no essential way the argument of my earlier paper. For instance, I continue to hold that the individual seller is isolated under what Bishop calls differentiated competition; also under pure competition; and that the essential distinctions are between heterogeneity and homogeneity, isolation and nonisolation. The implications of this conclusion are decidedly different from those of Bishop's classification, especially when the "loose ends" of this latter are taken into account.

The coefficient proposed by Bishop as an indicator of oligopoly, *viz.*, $-E_{ii}/E_{ji}$, takes us back to the familiar "numbers" criterion for "well-defined groups" of sellers of equal size with perfectly symmetrical relationships between them; and it is interpreted as a "numbers equivalent" where these conditions are not met (p. 798). It is, as Bishop points out, not "perfectly

[9] In both directions and for completeness, of course, with respect to *all* elements of the problem, such as price, quantity, product, selling outlays, etc.

[10] This would include also the cases where some of the coefficients involved were zero and others were nonzero. For instance, in Bishop's case where the "own" elasticity of firm i's demand curve is high (*cf.* p. 911, above), the substitution of q_i for p_i in the cross-coefficient converts it from large to very small.

[11] A number of the factors which help to explain it are mentioned in *Monopolistic Competition*, Ch. 3 *passim*, esp. pp. 48-53.

[12] *Monopolistic Competition*, p. 83. (*Cf.* also p. 150). Triffin's translation of this statement into mathematics (*op. cit.*, p. 102), out of which his coefficient developed, certainly leaves much to be desired.

general," since it "breaks down in the case of literally homogeneous products." Hence in his classification "the limiting case of perfect homogeneity [is] not represented"—the nearest we get to it is "near-homogeneity." It is therefore necessary outside of the table to distinguish between pure competition and pure oligopoly, and between differentiated competition and "pure monopoly" (in the sense of an isolated seller). These "loose ends" involve major differences with my own classification which are perhaps more important than those contained within the table, and the reader will have to judge them for himself. The distinction between "differentiated competition" and "pure" (*i.e.*, isolated) monopoly involves the "industry" concept which, however useful it may be in particular problems, seems to me a delusion for this purpose. My own reasons for avoiding the "industry" concept and for approaching the oligopoly problem not as a matter of numbers but as a matter of the isolation or nonisolation of individual sellers, are explained at some length in my paper.

I should like to comment finally on one of the contrasts between Triffin and myself which is given great importance by Bishop—the question of whether costs should be allowed to influence a price cross-elasticity coefficient, or whether, on the other hand, this coefficient should, like "own" elasticity, be kept a matter of "pure" demand relations. On this issue Bishop sides with Triffin, holding that the effect of costs should be ruled out, and he has harsh words for those of the opposite opinion, of which I seem to be one.[13] The issue is dramatized by the common view that under pure competition the coefficient is zero if rising marginal costs are allowed, and ∞ if they are not allowed, to limit the increase in sales of the firm which shades its price. It appears to me now that neither of these conclusions is as certain as has generally been thought, and that the answer will in each case depend upon some further questions of interpretation.[14] But let us first look into the question of whether the effects of cost considerations must necessarily be ruled out of price coefficients on general grounds, regardless of the market structure involved.

In arguing that costs should be excluded, Bishop holds in effect that there is a single "correct" answer to the question, and this I cannot accept. Both types of coefficient seem to exist in the sense that they can be defined, and it is simply a question of their relative usefulness. He argues furthermore that the answer must be the same for both elasticity and cross-elasticity, *i.e.*, that since it is absurd to "invoke supply restrictions" with respect to elasticity, it is necessarily so with respect to cross-elasticity (p. 792). But this argument by analogy makes no sense to me; and no one so far as I know has proposed

[13] I agree with Bishop that the "other combatants" should not be neglected (p. 785, n. 11), but cannot take the space here to discuss them. Incidentally, Triffin's use of profits in what appears to be his final and "general" statement on defining the oligopolistic problem (*op. cit.*, p 115) clearly includes costs.

[14] In particular, the distinction between the *magnitude* of the adjustment and the value of the coefficient as a derivative is essential. The problem can be formulated in such a way that the rising cost curve of the firm i (which shades its price) reduces $\Delta q_j/q_j$ to zero *by limiting the magnitude of the adjustment,* but without affecting the value of the coefficient itself.

modifying elasticity of demand by introducing "supply restrictions." The fact is that cross-elasticity is *not* a relationship between the demand functions of two firms, and therefore can never be "pure" in this sense.[15] The coefficient between two firms cannot be discovered from their two demand curves because it depends also on such matters as the number of "other" firms and a complex of interfirm relationships not contained in the two curves. Neither one of their demand curves is in fact involved in the coefficient in any direct sense. When firm i shades its price there is no movement along its demand curve so far as *cross*-elasticity is concerned: i's increment of sales does not appear in the coefficient. As for firm j, what is involved is diminished sales at the *same* price, in other words a redefinition of its demand function rather than a movement along it. In the broadest sense, cross-elasticity involves "the rest of the economic system," and in describing the effect on q_j of a change in p_i there seems to be a good case for describing it as it actually is, rather than ruling out any part of the restraints which the system has imposed upon it in transmission from i to j.[16] Bishop speaks critically of "those writers who measure cross-elasticity, following an assumed price cut, not in terms of customers' willingness to buy, but in terms of the firm's willingness to *sell*" (p. 792, italics his). This is incorrect. The coefficient as used by the writers in question does measure the amount which j's customers are willing to buy (from j, naturally) as the result of a price cut by i.

I shall not take the space here to discuss adequately the behavior of the price cross-elasticity coefficient under pure competition, for the reason that this appears to be a rather complicated problem under the theory of limits, with several different answers depending on how it is conceived mathematically. To state only three possibilities, the coefficient may be defined as (1) the limiting value of $p_i \cdot \Delta q_j/q_j \cdot \Delta p_i$ as $\Delta p_i \rightarrow 0$, the number of sellers and "own" elasticities being either (a) very high but finite, or (b) infinite; or (2) the limiting value of (1) as the number of sellers approaches ∞, "own" elasticities being given; or (3) the limiting value of (1) as "own" elasticities approach ∞, the number of sellers being given. The list is not exhaustive, and it should not be overlooked that, under certain definitions of the problem, numbers and elasticities will be functionally related. It seems doubtful if any one solution can be designated as *the* "correct" one, and doubtful therefore whether the price coefficient, which changes from 0 to ∞ and back again to indeterminate-

[15] Perhaps the elasticity of substitution between two commodities might qualify as "pure" in the sense of having to do only with substitutability. It is, of course, a completely different concept from cross-elasticity of demand, although I believe there is much confusion on this point. As a simple example, the elasticity of substitution between two brands of canned peas may be very high, but if there is a "large number" of other similar brands, cross-elasticity of demand may be very low. Kaldor seems to go astray here (*cf.* "Market Imperfection and Excess Capacity," *Economica,* Feb. 1935, V, 35, n. 1).

[16] I do not mean to rule here that any particular kind of mathematical function or procedure is the "right" one, since I am in fact protesting against Bishop having done just this. Thus demand curves are not necessarily Marshallian, in the sense of being obtained by holding all other prices constant, and however defined, their elasticity may be measured. Similarly, there is no single requirement as to what must be held constant and what allowed to vary when cross-elasticity is measured.

ness with a slight flick in the definitions, may be usefully applied at all to this limiting case. For economics the important concept is isolation, and however the cross-elasticity coefficient may be evaluated under pure competition there can be no doubt whatever that the individual firm is isolated in the sense that it has no influence on any other firm.

Reply

My differences with Professor Fellner may be focussed on a single issue of central importance. Fellner maintains, in both his Tables I and II, that upward cross-elasticities must be zero between any two firms in atomistic competition (pure or differentiated); and he holds, similarly, that positive upward cross-elasticities necessarily imply oligopolistic interdependence. It is my view that cross-elasticities (upward and downward) may be positive, and indeed very large, without implying oligopoly. Specifically, cross-elasticities will be high between any two members of a large-number group when the products of the rival firms are sufficiently near the homogeneity pole. Fellner's conclusion (usually without the upward-downward distinction) has been the instinctively plausible one to many people.[1] Hence it is all the more important to emphasize the grounds for my different view. I do so by means of a numerical example.

Imagine 1,000,001 suppliers of physically comparable but very, very slightly differentiated products. Assume that the firms are all charging equal prices and selling equal quantities. Assume, furthermore, that if the ith firm's price is raised very slightly (with all other prices constant), all but a negligible fraction of the business lost by that firm is transferred, in equal amounts, to the 1,000,000 other firms in the group. This means that the change in q_i will be (approximately) 1,000,000 times the opposite change in any other group member's q_j—in both absolute and percentage terms. For example, if p_i is increased so that q_i declines by 1 per cent, each q_j will increase by (approximately) .000,001 per cent. This is the negligible impact of one atomistically competitive firm on its fellows. I propose to show that it does not necessarily imply a "zero" or negligibly "small" cross-elasticity.

Suppose, now, that the ith firm's own elasticity E_{ii} (up or down) is $-1{,}000{,}000{,}000$. To reduce q_i by 1 per cent, p_i need be raised by only about .000,000,001 per cent. Hence the cross-elasticity E_{ji} is approximately 1,000, since the .000,001 per cent increase of q_j is 1,000 times the initiating percentage increase of p_i.

Now I beg the reader who sits in judgment to contemplate: (1) this very large number of firms; (2) this enormous own elasticity, implying a remarkably close approach to product homogeneity; and (3) this very high cross-elasticity! Is this situation oligopolistic or not? If it is not, let us be rid once and for all of the tempting but quite erroneous preconception that high cross-

[1] Still another example of this view comes from R. L. Hall and C. J. Hitch: "If . . . cross elasticities . . . were not negligible, . . . the situation would thus be oligopolistic"—"Price Theory and Business Behaviour," *Oxford Econ. Papers*, No. 2, May 1939, p. 16.

elasticities necessarily imply oligopoly. Negligible impacts of one atomistic firm on another are not the equivalent of small, let alone zero, cross-elasticities.[2] What *is* small in any symmetrical, large-number group (with finite own and cross-elasticities) is E_{ji} *relative to* $-E_{ii}$.

Before considering the ingenious and challenging ways in which Fellner seeks to avoid these conclusions, I should like to plead guilty to two of his charges: (1) my classificatory scheme is stated in terms of "point" elasticities and cross-elasticities (based on smoothly continuous demand functions); and (2) I regard a large but finite number of firms in a group as sufficient to establish atomistic competition, by contrast with oligopoly. Fellner does not object to either of these practices separately; but he regards their combination as somehow invalid.

As to my use of "point" rather than "arc" concepts, this was also the practice of all my predecessors, including Fellner; for we all used partial derivatives in our elasticity and cross-elasticity notation. Point elasticities are convenient because of their lack of ambiguity. Specifically, they characterize a firm's situation with respect to even the smallest conceivable price-quantity change; and they also reflect, approximately, the implications of small, finite changes.[3] The underlying conception of smoothly continuous demand functions is, of course, an "idealization"—but again one that is familiar, convenient, and often (though not always) a defensible approximation of discrete reality. My basic disagreement with Fellner concerns his view that there is some tying clause in the theorist's contract that necessarily links this idealization with another quite different one—namely, an insistence that atomistic competition cannot exist with anything short of an "infinite number" of firms.

In the context of Table I, Fellner uses point cross-elasticities but refuses to classify a situation as atomistically competitive unless there is an "infinite number" of rival firms. He would thus classify my numerical example, above, as an instance of "differentiated oligopoly." As long as Fellner remains within the context of his Table I, a million suppliers of perfect or near-perfect substitute products are just a million oligopolists. I regard such situations as constituting either pure or near-pure competition.

To Fellner, the mere use of point elasticities and cross-elasticities by the analyst implies an assumption of "infinite sensitivity" on the part of the firms, which in turn would imply (in his view) that any finite-number group is necessarily oligopolistic. Several methodological questions of some subtlety are involved here; but the main point, it seems to me, is that Fellner here confuses the mere use of a convenient *analytical tool* (point elasticities) with an unjustifiably stringent *empirical assumption* (that, if a firm can detect even the

[2] Naturally, cross-elasticities are not *necessarily* high in atomistic competition. Even when products are still very nearly perfect substitutes, E_{ji} will be very low provided that the number of firms is sufficiently large. In my numerical example, E_{ii} need be changed only to $-1{,}000$ in order to reduce E_{ji} to .001.

[3] It is for this reason that there is no inconsistency in drawing conclusions about the consequences of small finite price changes in the light of elasticities that are based on infinitesimal price changes. But I cannot accept Fellner's contention (pp. 905-06) that the "valid content" of my article is *limited* to a context of "finite price changes."

smallest effect on itself of another firm's action, its reaction will necessarily be such as to establish oligopolistic interdependence).

Oligopolistic and atomistic *behavior* are distinguished according to the presence or absence of effective collusion. We merely try to predict the outcome of that "behavior" test by means of such "structure" tests as the number of firms.[4] If "numbers" are sufficiently large, we infer (empirically) that any relevant change of business decision by firm i will have, at most, a "negligible" impact on j; and we then conclude (empirically) that j's reaction, if any, will also be "negligible." It is not necessary that either the initial effect or the reaction be literally "imperceptible," but only that the interfirm repercussions be negligible *even if perceived*.

For example, a purely competitive firm will typically affect price ever so slightly if it changes its output substantially; but the situation will still be purely competitive, for all practical purposes, if the demand schedule relevant for the firm's output decision differs only negligibly from the strictly horizontal. This does not require that the change of that firm's output will have literally no effect on the outputs of the other firms, but only that the reactions of those other firms must not be such as to destroy the approximate horizontality of the relevant demand facing the one firm.[5] The main point is this: if the negligible impact of any one firm on its fellows gives rise to only microscopic, "passive" reactions, there can be no significant degree of oligopolistic interdependence. The equilibrium position of each firm will then differ only negligibly from what it would be if the effects of one firm on another were regarded as wholly imperceptible.[6]

[4] Alternatively, when groups are not well-defined, symmetrical, and isolated, I use the concept of a "numbers equivalent"—as a substitute for dubiously meaningful, actual numbers. Then $-E_{ii}/E_{ji} = n_i - 1$ implies that the effect of a change of p_i on q_j is *as if* the two firms *were* members of an ideally symmetrical, isolated group of n_i firms.

Fellner thinks that my choice of "numbers equivalent" as a name for this concept "may not be fortunate" (p. 909). My reason for that choice is that the *analogy* to the number of firms in a well-defined, symmetrical group is intuitively meaningful. On the other hand, because a "numbers equivalent" is applicable "even when there is no distinct grouping of firms" ("Elasticities, Cross-Elasticities, and Market Relationships," *Am. Econ. Rev.*, Dec. 1952, XLII, 789 and 798-99), the concept is in no way dependent on the "industry concept" (*cf.* Chamberlin, pp. 913-14).

[5] Naturally, the demand relevant for a firm's price-output decision is not, in general, a *ceteris paribus* demand; but it is an essential condition of atomistic competition (pure or differentiated) that the other-prices-constant demand be a very close approximation of the relevant demand. For example, if all the members of a purely competitive group have *fixed supplies*, the relevant demand facing the ith firm has an elasticity equal to n_i times the industry-demand elasticity, where n_i is the ratio of industry quantity to the ith firm's quantity (*cf. op. cit.*, p. 795, esp. n. 26). With *variable supplies* (upward-sloping marginal costs), the relevant elasticity is even higher; for a given increase of q_i, lowering price very slightly, will then reduce all the q_j's microscopically, and so cause price to fall even *less* than in the case of fixed supplies (*op. cit.*, p. 797, n. 28).

Although "negligible" and "imperceptible" are often used loosely as synonyms, I feel that it is neither necessary nor desirable to make atomistic behavior depend on the myopia or the "limited sensitivity" of the firms, as Fellner would have it (p. 904, esp. n. 12). In my view, the mere "awareness" of *very small* effects is not likely to give rise to oligopolistic *behavior;* and it is this presumption as to behavior, it seems to me, that is the proper focus of market classification.

There is a world of difference between such microscopic, passive reactions and oligopolistic interdependence. The typical oligopolistic reaction to a price cut is not just passive, but retaliatory. That is, it is designed to discourage such price cutting in the first place, even at the immediate cost of the retaliator's hurting himself even as he seeks to discipline the aggressor. Oligopolistic collusion, explicit or tacit, accordingly implies a *reluctance* to make certain aggressive moves *solely* because of an expected or feared reaction from one or more rivals. Hence an oligopolistic "equilibrium" typically implies that the firms are at positions significantly different from those that would be implied if the firms were to make their business decisions on an assumption of negligible reactions from rivals.

The likelihood that collusion will be attempted—and if attempted, successful—depends not only on the mere perceptibility of the effects of one firm's actions on another, but on the *magnitude* of those effects and the *character and magnitude* of the reactions. Least of all can the likelihood of oligopolistic behavior be prejudged simply on grounds that the analyst chooses to use point elasticities (or arc elasticities that are based on very small finite price changes). I confess I am somewhat surprised to have to rebut a view that the principles of *Competition Among the Few* are now automatically applicable to "competition among the few million" simply because the author used point elasticities.

I also have misgivings about Fellner's use of the concept of an "infinite number" of firms. Some limits can be reached (*e.g.*, an absolutely homogeneous product). Others cannot (*e.g.*, an "infinite number" of firms). "Infinity," in this context, is not a "number" but simply an implication that there is no finite limit. In Fellner's Table I, point cross-elasticities (upward and downward) are *infinite* when identical products are supplied by any finite number of firms. But he also believes that, with an "infinite number" of firms, the upward cross-elasticities will be uniquely *zero*. Now if this is to mean anything at all, it must mean that the upward cross-elasticities *approach* zero as the number of firms grows indefinitely large. But this they do not do, on the testimony of Fellner's own Table I. With strictly homogeneous products, the leap from infinite to zero cross-elasticity takes place only in a never-never land of "infinite numbers" of firms. Hence it is not consistent with the basic principles of taking a limit.[7]

Provided that there is a very large number of producers of a homogeneous product, I also think that either the Cournot model or the Bertrand model is quite acceptable (again *cf.* Fellner's n. 12). These two models then give approximately the same results. They give significantly different results, and are both unacceptable, only when the number of firms is small. In other words, neither Cournot nor Bertrand had a satisfactory theory of *oligopoly;* but they both did have satisfactory theories of *competition.*

[7] In the foregoing paragraph I have willingly repressed my own misgivings about the determinacy of cross-elasticities when there are three or more suppliers of absolutely homogeneous products (*op. cit.*, pp. 793-94). I am willing to follow the convention that Fellner seems to accept—namely, that any change in q_i will affect oppositely, to at least some extent, every other q_j in the group. Then the cross-elasticities within the homogeneous-product group are all infinite no matter what the number of firms—just as the cross-elasticities *approach* infinity when product homogeneity is merely approached, for any given number of firms.

A fundamental logical trouble that has afflicted cross-elasticity pronouncements from the very beginning is that two kinds of limit are involved: (1) if own elasticities are constant and finite (because the product is not strictly homogeneous), a steady increase in the number of firms in the group does imply a steady *decrease* of cross-elasticities toward *zero* as a limit (never actually reached); and (2) if the number of firms is constant, an approach to product homogeneity implies a steady *increase* in cross-elasticities toward *infinity* as a limit.[8] Fellner's mistake, as I see it, is in supposing that the number-of-firms limit (which cannot be reached) must be dominant over the product-homogeneity limit (which can). If *both* of these limiting processes are operating simultaneously, no one can say *in general* how the cross-elasticities will behave.[9] But cross-elasticities may assuredly be either high or low no matter how many firms there are in the group. It all depends on the number of firms *relative to* the degree of product homogeneity (as reflected specifically in the own elasticities).

In the context of Table II, Fellner relaxes his requirement that there must be an "infinite number" of firms for atomistic competition; but now he insists that cross-elasticities must be based on "*ad hoc* selected finite price changes." He also specifies the treatment of "subjectively unnoticed ('negligible') quantities as zeros." When products are homogeneous (absolutely or practically) and firms are many as in my opening example, a negligible increase of p_i has a negligible effect on q_j. Hence the upward cross-elasticity would be "negligible" over "negligible," which at least suggests—if it means anything at all—the indeterminate form of zero over zero. More fundamentally, as long as Fellner refuses to measure "neglibles," he has no grounds for asserting anything whatever about their ratios to one another.

Fellner would say, however, that his upward "incremental" (or arc) cross-elasticities are uniquely zero in my numerical example. Clearly, this is not just a matter of "point" versus "arc" elasticities; for my own example was stated in terms of a finite price increase, and the "incremental" cross-elasticities turned out to be very high. Fellner gets his result of a "zero" cross-

[8] For a welcome expression of essentially the same view, see Chamberlin's limiting processes (2) and (3), p. 915. Fellner, on the other hand, implies a denial that the latter limiting process is a continuous one. Defending a position taken earlier by Chamberlin, he maintains that "while cross-elasticity may be infinite in the undifferentiated large group, it falls to zero with the least differentiation" (p. 902, n. 4). It falls to zero, say Fellner, because "in the event of the least differentiation the sales-increment of the price-reducing firm can be made smaller than *any* finite magnitude provided that the price reduction becomes small enough." This remarkable argument implies that *every* finite derivative and elasticity is zero. My opening numerical example provides my own positive demonstration of nonzero and *high* cross-elasticities in the "large group . . . with the least differentiation."

[9] In the second paragraph of n. 4, p. 902, Fellner implies agreement with this view; but he fails to recognize that it undermines his central thesis as to the uniquely zero upward cross-elasticity in pure competition.

Although Chamberlin now seems to be with me for the most part on these questions, our agreement is still not complete. His limiting process (1) on p. 915 implies that there is a limiting value of the expression given there when "the number of sellers and 'own' elasticities" are "infinite." This is the same meaningless concept for which I am criticizing Fellner.

elasticity only by specifying that the price increase must *not* be negligible, even though a much smaller—and specifically negligible—price increase must be sufficient to remove the homogeneous-product supplier from the market. In my example, something on the order of a .000,000,1 per cent increase in p_i would very likely be enough to reduce q_i by 100 per cent.[10] That would increase each of the q_j's of the 1,000,000 other firms in the group by about .000,1 per cent; so the cross-elasticities would still be on the order of 1,000. Hence, to reduce the cross-elasticities even to 1, Fellner would have to specify a price increase about 1,000 times larger than necessary to remove the price-raiser from the market; and to reduce the cross-elasticities to .001, he would have to specify a price increase about 1,000,000 times larger than necessary.

Although Fellner does not indicate just how arbitrary his "*ad hoc* selected finite price changes" are, they are "*ad hoc* selected" simply to make the upward cross-elasticities sufficiently small for his own taste—when he wants them to reveal atomistic competition. This reminds me of Humpty Dumpty's practice: "When *I* use a word, it means just what I choose it to mean—neither more nor less." When Fellner measures an incremental cross-elasticity under conditions of pure or near-pure competition, its magnitude is just what he chooses it to be.

In my own classificatory scheme, despite Fellner's strictures, there is no *general* need for a distinction between "upward" and "downward" elasticities or cross-elasticities. Such a distinction would be needed only if the firm were to operate at a point where there is a "kink" or discontinuity of slope in its demand curve.[11] Such a "kink" in a consistently other-prices-constant demand curve results, for example, when some buyers regard the products of two or more firms as homogeneous, while others regard them as differentiated.[12] Because this phenomenon implies that the demand slope is first negative and then changes abruptly to zero at a critical point, no firm will actually operate at that point. Rather, some firms will compete for the homogeneous-product business, and thus be somewhere on their demands' horizontal stretches, while others may be content to exploit their demands' downward-sloping portions. Depending on the number of firms, those with locally horizontal demands are, in effect, in situations of either pure competition or pure oligopoly. On the other hand, *smoothly continuous* demand functions always imply *equal* upward and downward elasticities, both own and cross. That is, the point

[10] This implies that the demand for the *i*th product is approximately linear. I am assuming—as is certainly possible—that the price increase necessary to reduce quantity by 100 per cent is approximately 100 times the price increase that reduces quantity by 1 per cent.

[11] The familiar, oligopolistic "kinked" demand is not germane here. That is based on an other-price-constant demand for price increases and an other-prices-changing demand for price decreases. Fellner and I are both talking about other-prices-constant demand relationships.

[12] *Cf.* A. J. Nichol, "The Influence of Marginal Buyers on Monopolistic Competition," *Quart. Jour. Econ.*, Nov. 1934, XLIX, 121-35; Alfred Nicols, "The Rehabilitation of Pure Competition," *Quart. Jour. Econ.*, Nov. 1947, LXII, 31-63; Joe Bain, *Pricing, Distribution and Employment*, rev. ed. (New York, 1953), pp. 353-55; and Ron Hieser, "A Kinked Demand Curve for Monopolistic Competition," *Econ. Rec.*, May 1953, XXIX, 19-34.

elasticities are exactly equal; and the arc elasticities based on sufficiently small price changes are approximately equal.[13]

Naturally I am gratified that Professor Chamberlin now agrees with me that the cross-elasticities E_{ji} and E_{ij} are not, by themselves, a reliable indication of the presence or absence of oligopoly. It was because he had proposed these cross-elasticities as his test for oligopoly that I characterized his classification as "unsuccessful."[14] I regret, however, that I have left him with only a negative conviction of the "complexity" and "treachery" of cross-elasticities "as a measure of anything" (p. 911); for—when products are differentiated, however slightly—the *ratios* of cross-elasticities and own elasticities do seem to provide the oligopoly test for which he has been unsuccessfully searching. As for my having adopted E_{ii} as my own preferred criterion of product homogeneity-heterogeneity, I am happy to acknowledge that I did indeed follow Chamberlin in this.

In his Talloires paper, as Chamberlin now says, he criticized "Robert Triffin's classification of the problems of monopoly and competition in terms of cross-elasticities alone" (p. 910).[14a] He also feels that I exaggerated the contrast between Triffin's views and his own; and, by way of illustrating this, he says that I "ignore altogether Triffin's very substantial use of price cross-elasticity . . . in testing for oligopoly" (p. 912). It is my view, on the contrary, that Triffin relied principally on the quantity cross-elasticity e_{ji} in testing for oligopoly. His only use of the price cross-elasticity E_{ij} for that purpose, it seems to me, was in conjunction with e_{ji}—in his "circular test."[15] Hence I also feel that Chamberlin's critique of Triffin's schema—by concentrating solely on E_{ij}, to the neglect of e_{ji}—was seriously incomplete. I say this only to emphasize that Chamberlin's objections to the contrasts that I found between Triffin's discussion and his own do indeed reflect fundamental differences between us in our understandings of Triffin.

Several matters discussed by Chamberlin seem to be mainly if not entirely verbal. He wishes "to bring into a single category the two concepts of an 'isolated monopolist' and of a single seller in the 'large-numbers-differentiated-product' case"—because "these two concepts come to the same thing" (p. 911). Everyone agrees, I think, that these two cases are alike to the extent that they are both nonoligopolistic. Beyond that, it seems to me mischievous in the extreme to suggest that there are no significant differences between them. The traditional, simple monopolist is "isolated" because there are *no* significantly close substitutes for his product. The differentiated competitor is "iso-

[13] I detect no belief on Fellner's part that "kinks" are as universal as his "upward-downward" distinctions would seem to imply. The one such contrast in his Table I, I have argued above, is the result of faulty logic. The omnipresent contrasts of this kind in his Table II are manufactured by his arbitrary use of incremental cross-elasticities.

[14] Although at one point Chamberlin might now seem to be minimizing his former "faith in cross-elasticity" (p. 910), there is no question that he did use that concept to distinguish (in his own terminology) "isolated selling" and "nonisolated selling."

[14a] I assume from the context of the Talloires paper that this refers only to *price* cross-elasticities.

[15] Triffin, *Monopolistic Competition and General Equilibrium Theory* (Cambridge, Mass., 1940), pp. 104-5 and 134.

lated" in a very different sense, because he is lost in the crowd of so *many* suppliers of relatively close substitutes that his relationships to his competitors are again nonoligopolistic.[16]

Another of Chamberlin's verbal problems concerns just this ambiguity of the word, "isolation." For Triffin, "isolated selling" is associated with "pure monopoly," and *not* with atomistic competition, whether pure or differentiated. Yet for Chamberlin, isolation and nonoligopoly are "revealed" as the same thing (p. 912). The correct word is "defined"; and we can take our choice in following either Triffin's or Chamberlin's definition.[17]

The last verbalism is the term, "pure monopoly." An overwhelming majority of economists prefer to equate this with the traditional concept of monopoly. Thus we have not followed Chamberlin's own distinctive definition of "pure monopoly"; but we do not feel that we have "perverted" anything in setting up simply a different definition from his. Nor does the redefinition seem "disastrous" (p. 912, n.7). I, for one, rather feel that it is healthy to resist the theoretical imperialism by which Chamberlin would swallow up traditional, simple monopoly as just another species of monopolistic competition.[18]

I have little to add to my earlier discussion on "the question of whether costs should be allowed to influence a price cross-elasticity coefficient."[19] I do believe, however, that it is just as ill-advised to "invoke supply restrictions" with respect to cross-elasticities of demand as Chamberlin concedes it to be with respect to "own" elasticities. The generalized demand for the ith firm's product, on which both E_{ii} and E_{ij} are based, is of the form: $q_i = q_i(p_1, p_2, \ldots p_i, \ldots p_j, \ldots p_n)$. The derivatives, $\partial q_i/\partial p_i$ and $\partial q_i/\partial p_j$ (or the elasticities, E_{ii} and E_{ij}) are then precisely analogous to one another.[20] Moreover, the naked expressions, $E_{ii} = (\partial q_i/\partial p_i)(p_i/q_i)$ and $E_{ij} = (\partial q_i/\partial p_j)(p_j/q_i)$, have perfectly definite meanings; and they cannot be made to stand for anything else except by some more Humpty-Dumptyism.

[16] I also feel that it is perfectly feasible to distinguish the pure monopolist from the differentiated competitor, in terms of the frequency distribution of cross-elasticities (*op. cit.*, pp. 786-87 and 799-800).

[17] Chamberlin also says: "in using cross-elasticity coefficients to distinguish isolation from nonisolation, I have merely followed Triffin. . . ." (p. 912). But, since his definition of isolation is completely different from Triffin's, I cannot agree that my criticism of the "use of price cross-elasticity as a test for *oligopoly* is equally applicable to Triffin's use of it as a criterion for *isolation*. . . ." My criticism would be so applicable only with respect to "isolation" as *Chamberlin* defines it.

[18] According to Chamberlin, "the now prevalent terminology" implies that any nonoligopolistic seller "would be a 'pure' monopolist"—since such a seller is "isolated as truly as the traditional monopolist" (p. 912). It seems peculiar, to say the least, for Chamberlin to attribute this view to his opponents—since it is he who would blur the distinction (which the rest of us seek to maintain) between the traditional monopolist and the nonoligopolistic species of monopolistic competitor.

[19] Chamberlin's discussion is on pp. 914-15; my own is *op. cit.*, pp. 790-92.

[20] The "own" concept is a "diagonal" term, and the "cross" concept is an "off-diagonal" term, in the matrix of either the derivatives or the elasticities, respectively.

Nor is there any notable significance in the otherwise perfectly correct fact that a change of p_i represents a *movement along* a demand of the abbreviated form, $q_i = f(p_i)$, while a change of p_j may *shift* that same $q_i = f(p_i)$. When demand for the ith product is more broadly formulated, as above, that generalized demand function is not "shifted" by changes of either p_i or p_j.

There would be no objection whatever to Chamberlin's defining any alternative concepts that he pleases—with or without reference to costs. When he writes down either partial derivatives or the elasticities based upon them, however, I would hope that he might specify—as he has not done in the past—the *functions* he is differentiating. Only in that way can we judge (a) the meaning and (b) the usefulness of the concepts he may have in mind. In particular, if he thinks he can define meaningful and useful elasticities of demand (including cross-elasticities) by "invoking supply restrictions," by all means let him come forward with a *specific* definition.

BOOK REVIEWS

Economic Theory; General Economics

Utility and All That, and Other Essays. By D. H. Robertson. (London: George Allen and Unwin. New York: Macmillan. 1952. Pp. 206. $3.50.)

In this volume are assembled sixteen of Sir Dennis Robertson's essays written from 1945 to 1951. They are arranged in four groups dealing with general theoretical matters, with problems of interest and capital, with international economic affairs, with money and banking. The essays vary greatly in length and significance, from one paper which attempts a reorientation of the theory of interest to a number of brief occasional notes. All of the essays afford valuable insights; all are delightful reading for the author's Puckish jibes and asides; and all of them cut through jungles of theoretical pretense or confusion with the keen hard blade of common sense.

The last of these qualities stands forth conspicuously in the first essay, the subject of which has been taken for the title of the collection. Reviewing the recent literature on consumers' surpluses and welfare, Robertson finds that Hicks' and Allen's indifference functions and "revealed preference," designed to operate behavioristically and to dispense with one dimension called cardinal utility, actually make matters more complex. Cardinal utility keeps reasserting itself, and it is better to recognize it explicitly, as Marshall does. The reviewer agrees with Robertson that introspection justifies the concept of cardinal utility; but operationally the difference may not be great. Anyone who prefers to operate with ordinal concepts could read the familiar Marshallian figures correspondingly, since the monetary expression of utility may be in either relative or absolute terms.

In the same essay, Robertson indicates his belief that welfare economics should be able to steer a course somewhat between the one extreme, represented by Myint, who imagines a measure of *social* gain or loss possible even with changes in distribution, and another extreme, represented by Samuelson and Little, who are very sceptical about the possibility of measurement. Most readers will sympathize with Robertson here. They may wish, however, that he had pressed further his suggestion that the maintenance of incentive enters into the problem of maximizing social welfare. Hitherto inequality of distribution has been the rock upon which aggregate social welfare has split up. But if we limit the theory to *functional* inequalities—inequalities necessary to "evoke and maintain" correct relative factor supplies (in Hobson's phrase)—and if we suppose with Lange that the distribution of the capacity to enjoy income is a random one in any fair sample of the population, we approach fairly closely to a social maximum of welfare. Other elements, such as resentment of inequality, would still make precise quantification impossible; but in many situations they might be sufficiently unimportant to permit the desirable *direction* of policy toward maximum welfare to be seen.

In "The Economic Outlook" written in 1947 Robertson, with what in retrospect amounts to prophetic revelation, considers the pitfalls of planning in the English postwar economy. "Years of lowbrow talk about production for use and not for profit, fewer but intenser years of highbrow talk about the humbug of finance and about investment breeding its own saving have left us with a formidable web to unwind" (p. 56). As an antidote to these errors, he quotes the sentence of Marshall that "Progress mainly depends on the extent to which the strongest, and not merely the *highest* forces of human nature can be utilized for the increase of social good." He also broaches the profound question whether there is any final and ultimate distinction between democratic and totalitarian planning.

Robertson's presidential address to the Royal Economic Society, "On Sticking to One's Last," takes issue with a former president, Mr. Hawtrey, and denies that the economist should concern himself with other objectives than economic welfare, such as National Prestige, and Employment (as an end in itself rather than as a means of earning income). The economist is bound to point out, for example, such homely facts as over- or undersupply and the wastage they entail, even if these conditions result from attempts to serve some high principle of moral justice. Conversely he must also distinguish between useful injustices and useless or harmful ones.

The end piece of the first group of essays is Robertson's half-mischievous review of the first volume of *A Survey of Contemporary Economics*. For the "headmaster" of this school (in Robertson's terms) to appraise this review would probably cater only to rare antiquarian interest. For that rare case, the "headmaster" may perhaps be permitted one lapse into bad manners: to confess that Robertson has voiced many criticisms and evaluations of the several papers which the editor felt keenly but suppressed for the sake of decorum.

On the three papers constituting Part II, it will be necessary to bypass in the limits of this review the two occasional essays on "What Has Happened to the Rate of Interest" (December 1948) and "British National Investment Policy" (January 1952). Many of the author's *obiter dicta* transcend occasion, however. "We have got to the stage of admitting that it may sometimes be decent for wages to stop rising and for prices actually to fall, though the admission has still to be wrapped up in layers of witch-hunting formulae about wicked entrepreneurs" (pp. 95-96); and "a State which claims to control the rate of capital growth has undertaken a function for its precise manner of discharging which it will always find it difficult to offer any convincing explanation . . ." (p. 118).

The *pièce de résistance* of the volume, in many ways, is "Some Notes on the Theory of Interest," reprinted from the Williams honorary volume. Robertson supports the view that if net investments are being made, the marginal productivity of capital *always* stands above the rate of interest, and the rate of interest *always* stands above "myopia" or the marginal rate of time preference. If Robertson's first inequality means that there could be neither net saving nor net investment if (using Wicksell's terms) the natural and money rates of interest are equal, a good many contemporary theorists—rightly, I believe

—would disagree. Let the reader review Myrdal's critique of Wicksell's three criteria of equilibrium in *Monetary Equilibrium,* particularly the last pages dealing with the money-natural rate criterion.

Robertson's second inequality, the excess of the rate of interest over the marginal rate of "myopia," said to be necessary for net investment, involves two difficulties. In the first place, does this or does it not imply that even without net investment a positive rate of interest would be necessary to overcome marginal myopia (or time-preference)? In other words does "real myopia" entail a positive interest rate in a stationary economy? And if so, what gives myopia this characteristic? In the second place does myopia or time preference give hostages to the fallacious idea that saving is just "postponing consumption"? Are they rational or irrational, the latter being implied at the end of page 99? Do they have *any* meaning not better conveyed by the perfectly colorless phrase "the supply schedule of saving"?

Other parts of this essay, dealing with Keynes' liquidity preference and Kaldor's speculative theory of interest and Cassel's contributions, move upon firm terrain.

In Part III, the very short essay on the Terms of Trade will be perennially valuable for its lucid differentiation of various meanings of this term, and of the gains from the terms of trade and the gains of trade in general. But it would be too laborious to note all of the contributions of this small volume to theoretical insight and to practical common sense. These qualities are not quite separate matters from a sense of humor and a sense of modesty. Consult in the index the items "Tweedledee" and "Tweedledum" for one example among the many.

University of California, Berkeley

The Political Economy of Monopoly: Business, Labor and Government Policies. By FRITZ MACHLUP. (Baltimore: The Johns Hopkins Press. 1952. Pp. xvi, 544. $5.50.)

The Economics of Sellers' Competition: Model Analysis of Sellers' Conduct. By FRITZ MACHLUP. (Baltimore: The Johns Hopkins Press, 1952. Pp. xx, 582. $6.50.)

Professor Machlup's volumes on the economics of monopoly and competition will be highly appreciated by professional colleagues and students alike. These books may perhaps be viewed as two volumes of a single work even though the decision concerning the sequence of the volumes would have to be somewhat arbitrary. The general reader and the student of general economics will be interested mainly in *The Political Economy of Monopoly.* The book on sellers' competition deals with problems which are of interest primarily to the theorist and to the more advanced student who wishes to acquire proficiency in the theory of market relations. In one sense the book on monopoly is a more elementary "first volume" since some of its early sections may serve as a simple introduction not only to the volume itself but also to the theoretical analysis which is found in *The Economics of Sellers' Competition.* Yet in another sense the book on monopoly is the "second volume" without which

the work would be incomplete even for professional readers. It engages much more in the appraisal of *directly* significant problems than does its companion volume which is of "instrumental" character in that it presents, illustrates and further develops a technique of analysis.

The author's appraisal of market tendencies and of government policies is presented in such a way that the reader of *The Political Economy of Monopoly* becomes well acquainted not only with the author's views but also with the factual background of the problem and with the main arguments that can be advanced for and against Machlup's position. This is a substantial merit. The book contains excellent brief summaries of information on the degree of concentration in various industries, with the proper discussion of the fictitious accuracy involved in the data; of the history of anti-monopoly legislation and the significance of mergers; of existing pieces of legislation which promote producers' monopoly; and of labor policies and legislation. The specific conclusions which Machlup derives from this information will not be shared by all readers. But this will not limit the usefulness of the book because the summaries are sufficiently general to make it obvious that subjective judgment is required for reaching final conclusion.

Machlup is aware of the fact that no scientifically documented statement can be made on how much of the existing degree of concentration in the various industries is required for keeping them at a given level of economic efficiency. But while he acquaints us with both sides of the argument, he is nearly always willing to give the benefit of the doubt to the antimonopoly side. Multiplant expansion can in his view be accepted as an almost dependable sign of the growth of a firm beyond the size required for maximum efficiency on a given level of technology; substantial reduction of concentration would almost certainly have a favorable effect on further technological progress; and the reduction of competition in atomistic groups of producers by government interference is almost always unjustified. Hence Machlup suggests not only the vigorous enforcement of the present antitrust laws but he looks favorably also on strong additional measures for reducing the degree of concentration. These include tax policies which treat small enterprise more advantageously than the oligopolistic, and which discourage the accumulation of undistributed profits; freer international trade; a ban, with some exceptions, on intercorporate stockholdings; substantive patent reform; and possibly direct limitation of firm-size. Unionism he takes for granted but he feels that the noncompetitive character of the labor supply might make it desirable to regulate wages by government policy based on definite rules. Thus, in an economy with a stable general price level and high employment, the general level of money wage rates could be made to rise gradually in accordance with over-all economic productivity, while wage rates in specific industries would be allowed to increase at a greater or smaller rate according as there exists labor shortage or unemployment in a specific sector. By such regulation the misuse of monopoly power by unions could be avoided.[1] Antici-

[1] Machlup is inclined to the opinion that the relative share of labor in national income has shown a rising tendency but argues that this need not be a consequence of union activity because the stock of capital has risen more rapidly than the labor supply. If we consider

pating strong political resistance to such a scheme, Machlup describes the limitation of individual unions to specific areas as an alternative measure which would fit into his competition raising program.

In some ways the antimonopoly convictions of the reviewer are less general than those of Machlup. The agreement is complete as to the generality and the significance of the case against business practices of a "predatory" and "discriminatory" kind which by their very nature have the consequence of "artificially" excluding efficient rivals.[2] However, oligopoly that would survive a truly complete suppression of such practices presumably results from real economies of scale. The reviewer, unlike the author, doubts very much even the "theoretical possibility" of eliminating nearly all oligopoly power without sacrificing important technological and organizational economies. It is difficult to imagine fiscal or similarly general policies which would be based on the distinction between such concentration as is required for social efficiency and such concentration as is not. Also, to the reviewer comprehensive wage regulations seem undesirable in economies not operating under a rigid full-employment guarantee; and the alternative proposal to reduce the size of unions would, in his opinion, not change the inflationary potentialities of full-employment periods (nor the long-run trend in income distribution which seems dominated by forces other than unionism). But even readers who dissent from Machlup in these or in other respects should agree that he has presented us with a most lucid, useful and interesting discussion of the factors which must be weighed by anyone desiring to develop an articulate attitude toward problems of antimonopoly policy.

Turning now to *The Economics of Sellers' Competition* we should call attention to the subtitle of the volume which characterizes the author's method. He develops in this book a "model analysis of sellers' conduct." This book examines the consequences of sellers' behavior under alternative market conditions, on the working hypothesis that certain characteristics of these market relations and of entrepreneurial motivation are observable in pure form. Such model analysis can of course give only more or less realistic results. Some readers will place the emphasis on the *more,* others on the *less,* as we know from the extended controversy on marginalism in which the author of the book has played a leading rôle. The reviewer agrees that the traditional

long-run tendencies for the United States since 1920, limiting ourselves to privately produced income before direct taxes, and if we correct for the changing weight of employees in the labor force, I see no basis for the opinion that the relative share of employees has tended to rise. Various published statements by British economists suggest the absence of such a long-run trend for Britain too. In general, the effect of union-induced wage increases on the share of labor may well have become offset partly by price adjustments and partly by induced labor-saving innovations.

[2] Long-run social efficiency considerations may favor "artificially" excluding rivals who in a free market could be successful entrants at any moment of time. Patent legislation exemplifies this proposition. But it is not possible to develop a reasonable argument which would maintain that the social interest requires letting private groups practice "artificial exclusion" as they see fit. In some instances it is easy, in others difficult, to diagnose in practice a business policy as involving artificial exclusion of potential entrants, but the case against such policies seems entirely general to the reviewer as it does to the author.

method of which Machlup is a staunch defender remains significant. We lack analytical systems which would be sufficiently complete to permit of the quasimechanical use of theories for the explanation and the prediction of economic processes. The traditional method of rigorously analyzing simplified or purified processes in ideal models calls for *ad hoc* (informal) adjustments when we are concerned with real cases to which the assumptions apply merely with modifications. But while the method has been severely criticized on these grounds, it remains a fact that important insights have been derived from this type of analysis. In price theory so far no alternative models have emerged which, on a high level of generality, would yield less crude first approximations than those obtainable from the usual concept of market relations and the profit principle. Some of us may feel that Machlup occasionally underemphasizes (plays down) the limitations of the method of "strong cases" but no reader can justly accuse him of failure to call attention to the idealized or purified character of the situations with which he is dealing.

For oligopolistic markets the results of such analysis depend on particular assumptions concerning the nature and the extent of cooperation (collusion) between rivals. However, it is possible to describe main types of cooperative arrangement, and also to formulate reasonable hypotheses as to how the degree of cooperation typically varies with the characteristics of the industry demand (*e.g.,* its stability or predictability) and with other observable market characteristics. Machlup distinguishes carefully between different kinds of "cooperation" or "collusion" and gives a very revealing discussion of alternative types of oligopolistic coordination as well as of varieties of oligopolistic warfare.

The specific discussion of markets with atomistic and oligopolistic properties, with homogeneous and heterogeneous products, and with free and limited entry, is constructive, lively and systematic. The bearing of entry on market results is strongly emphasized. Quality competition and competition in sales effort receive detailed attention, as does of course price competition. Furthermore, in the course of his analysis Machlup directs his readers' attention to problems which frequently are overlooked or are relegated to other areas of economic theory. These include, among others, the nature of profit and rent concepts, the possibility or impossibility of extending the specific equilibrium theories relating to alternative market structures in the direction of general equilibrium theory, the historical race between diminution of the regional (spatial) monopoly element and increasing firm-size. While Machlup makes interesting observations concerning the effect of market relations on the rate of technological and organizational progress, the treatment which this problem receives is not commensurate with its significance.

In these two volumes Professor Machlup offers much in the way of clarification and individual contribution that will prove of considerable interest to the specialist. If to achieve this had been his only objective he could have expressed his ideas in fewer pages. However, at the same time, he wished to explain basic concepts of economic theory and also the content of his own contribution to other categories of readers, particularly to students. Yet I feel that on balance it would have been advantageous to shorten *The Eco-*

nomics of Sellers' Competition. Detailed explanation and illustration do of course help the reader, especially the relatively least expert group of readers which here will consist of advanced undergraduates. But the book inevitably presupposes the kind of interest in formal theory which, if it is real, goes with the ability to follow a more condensed presentation of problems. So far as classroom use is concerned, instructors will not find the book indivisible but they might not find it very *easily* divisible into more or less important sections, and the volume is too long for being used *as a whole* in a theory course which must include several other subject matters of great significance. On the other hand, I feel that it would have been unwise to shorten *The Political Economy of Monopoly* because the space which the book occupies as well as the author's expository skill is required to make the subject intelligible to a group of readers which in this case is potentially much wider. As for classroom use, here it does not matter much that in general courses there will be no time for working through the whole volume. Some instructors will want their students to know more about certain aspects, others about other aspects of the monopoly problem.

What really matters is that both books contain a wealth of material from which readers of many kinds may make selections to their substantial benefit.

WILLIAM FELLNER

Yale University

Psychological Analysis of Economic Behavior. By GEORGE KATONA. (New York: McGraw-Hill. 1951. Pp. ix, 347. $5.00)

So wide a field is encompassed by this book that a reviewer must resort to selective generalization, and this is fostered too by the long time that has elapsed since its publication. At this distance, the highly valuable pioneer job that Katona has done yields three major types of insight, and they concern basic problems in economic investigation and analysis that any serious practitioner must feel a need to consider. First, when the actor in economic life is man as modern psychology sees him, rather than the convenient figment—economic man—the job of the economist is altered and Katona indicates how. Second, certain familiar economic problems are considered in a fresh light. Finally, the changed job means a changed order of usefulness of various tools of study, and consequently methods are discussed explicitly and implicitly throughout the book.

On the first score, man is presented in the light of field and Gestalt psychology. Freudian insights, Katona believes, are, though valuable, not essential to the explanation of the economic behavior of groups. The mechanistic stimulus-response sequences of behaviorism are largely rejected. Man's objectives and motives are complex functions of the innate and the acquired. The organization of his behavior takes place within the psychological "field." "The field encompasses people's views of the past, their perceptions of the present, and their attitude toward the future" (p. 174). A notable aspect of this conception would seem to be that varying degrees of certainty and uncertainty are part and parcel of it. It means that the economist "instead of relating the environment to economic processes" directly, must "study the

relation of the perception of the environment, and of the perception of changes in the environment, to organized behavior" (p. 31).

What this basic injunction implies is then illustrated by treatment of a number of important economic problems. For most of them—investment, business cycles, and (in a particularly interesting chapter) profits—lack of pertinent data limits the discussion primarily to analysis. Even so the subjects are for the most part enriched by the insights that Katona brings to them, at the same time that his talent for the homely and concrete succeeds in making the discussions nicely illustrative of his general point. But in the section on consumption, especially on consumer saving, important empirical evidence is presented. The basic data were developed in extensive interviews of individual families done under Katona's direction at the Michigan Survey Research Center. Of the likely factors that might influence saving, information was collected about a number of economic ones—income, past income, purchases of durable goods, and holdings of liquid assets. But the theory also requires that perceptions and attitudes be studied, and consequently "attitudinal" variables—such as expectations about general economic conditions and future income, prices and purchases—were also included. Though I hold with Katona that subjective attitudes must affect economic actions, the showing of the surveys on this score does seem disappointing. I experience some difficulty in evaluating the data because of the failure to present information separately for relatively narrow income groups. Nevertheless, it seems clear that compared to the dramatic influence of major purchases of durables on saving (Tables XXX and XXXI), expectations play a picayune role (Tables XX and XXIX). Is the difficulty one of definition or of failure to differentiate between weakly and strongly held expectations or between those based on the economic scene rather than the stage of the family life cycle? Certainly these studies, like most good research, raise as many questions as they answer.

Finally, the book has much to say, implicitly and explicitly, about method. For when actions are caused by a wide variety of both subjective and objective factors, which are nevertheless believed capable of measurement, the proper way to study them is bound to differ from that appropriate to a world mechanistically conceived. For one thing, the complexity of relevant causation means that it is essential in economic analysis to proceed primarily from the particular to the general. Consequently, micro-economic studies assume critical importance. More specifically, "economic-psychological surveys" are advocated and described in several important sections. But only with some qualifications can analysis proceed from the particular to the general. For in studying "the factors contributing to specific decisions made under certain conditions, instead of attempting to arrive at generally valid answers regarding the how and why of all business procedures, . . . analysis is in need of guiding lines and hypotheses" (p. 214). One source of such guides is economic theory; another is psychology. From the latter, Katona derives a guide of which he makes extensive use—the dichotomy between acts involving habitual behavior and those entailing true decisions. I must say I find this a most unfortunate choice, in which the basic fact that most acts involve important elements of

both the habitual and the elective is lost. Corresponding distortion of economics seems to result. Similarly unfortunate is the sharp juxtaposition of decisions based on "sizing up" a situation and those based on "detailed calculations made on the basis of definite expectations, or of a range of probability distribution of expectations, or marginal calculus" (p. 249), which may constitute a projection into economics of the basic notion of Gestalt psychology. A similar cramping of economics may have resulted if the apparatus of the psychological field was responsible for turning the weight of attention from examination of how decisions to purchase (and then when to purchase) major consumer or producer goods evolve. Though Katona recognizes the importance of such work, especially in the field of investment, discussion actually does center on decisions or expectations as they exist at a particular time, however affected by visions of the past or future.

These are almost necessary weaknesses of first experiments with a difficult approach. And they are themselves instructive: they urge the importance of borrowing from psychology only basic quite noncontroversial conceptions, leaving lesser or newer ones to be used only when their applicability in a particular context is subject to test. It should then be possible, by virtue of severe abstemiousness, to make the marriage of psychology and economics one in which troth is pledged for better only. For better, certainly, is the utilization by economists of the skills of psychologists in framing and carrying out studies and in eliciting outside cooperation when this is required. For better, most clearly, is Katona's basic notion, the implications of which he demonstrates so forcibly, that man's perceptions, attitudes and structuring of external reality are a prism through which the light of economic fact must pass before it activates response. This notion must deepen and broaden economic work wherever it penetrates.

RUTH P. MACK

National Bureau of Economic Research

L'objet de l'économie politique. By HENRI GUITTON. With *Observations* of Léon Dupriez and Francesco Vito. Bilans de la Connaissance Économique, Vol. II. (Paris: Lib. Marcel Rivière et Cie. 1951. Pp. 200. 450 fr.)

The amorphous philosophical discontent about the scope, rôle and nature of political economy has not yet called forth much writing in the Anglo-Saxon countries. Elsewhere the situation is different, and this volume is an excellent representation of what might loosely be called the economic viewpoint of a certain section of continental Europe. Most economists will find it difficult to understand many of the concepts in their application to political economy, *e.g.*, *science morale*. Much less will they sympathize with them. This should not be enough to condemn the book, for the problems of ethics, morality, and the ultimate ends of man have always occupied political economists even though they usually exclude this speculation from their economic writings.

The title of this book has been rendered elsewhere as *The Object of Political Economy*. This is misleading. Since the French word *"objet"* is so rich in meaning it is only fair to the authors to note their connotation of

"subject matter" or, in German, *"Gegenstand"* or *"Inhalt."* The heart of the book is an interesting discussion of about one hundred pages, quite in line with the title, by Professor Guitton of the Faculty of Law of the University of Dijon.

After a brief introduction the first section is devoted to a rather critical review of various conceptions of political economy, dominated by what the author calls the image of the physical sciences. Writers in this vein, like Fisher, Nogaro, Pareto, Marshall and Weiser, are generally held to feel that political economy is like the other sciences, *"amorale, générale, indifférente."*

In the second section and conclusion, Guitton sketches his conception of the new and developing concepts in this field. Very briefly, the new science of economics will be one of the first *"sciences supérieures"* which will work out its own new techniques and become practically a new type of knowledge. His attempt is one of synthesis that will aid this development leading to a new human science of action. This is not held to be entirely in opposition to the older conception because writers often have expressions of both ideas in their works. It is maintained that perhaps our most urgent task is that of developing our science to be better adapted to the present and future. Unfortunately, despite the forcefulness of the plea for such a science, not much is said about how it could be achieved.

Both Dupriez and Vito agree in the main with Guitton. Dupriez, professor at the University of Louvain, emphasizes three questions: the rôle of rationality in economic activity, the value of certain analogies, and the normative character of economics. One of his conclusions suggests the viewpoint of the welfare economists—we must judge economic activity increasingly from the point of view of the group rather than from that of the individual. He goes further than most of them when he speaks of *"l'intervention politique."*

Professor Vito, of the Catholic University of the Sacred Heart of Milan, continues the discussion of rationality in economics but in the unusual way of attempting to define what irrational activity might be. He concludes by stating that there are already signs of a transition from *"neutralité"* to *"humanisme."*

The annotated bibliography, a feature of the series, has been expanded in this volume to include articles. This section of more than one hundred items is alone enough to make the book valuable. It includes works in at least five languages representing all important schools of thought.

Professor Guitton has achieved his goal of a synthesis. The success of this achievement can be evaluated only in terms of the value system of the reader. Even those who do not share the opinions of the author will find the book provocative.

Peter R. Senn

Wright Junior College, Chicago, Illinois

Die Konkurrenz und ihre Fehlentwicklungen, Untersuchungen über die Störungen der Marktwirtschaft. By Burkhardt Röper. (Berlin: Duncker & Humblot. 1952. Pp. 243. DM 14.60.)

This monograph by Röper, a younger member of the faculty of the Univer-

sity of Hamburg, concerns itself with the competitive market economy and its maldevelopments. The exposition is simple, nonmathematical, consciously avoiding much modern refinement, though aware and appreciative of basic modern literature. Monopoly and oligopoly, into which competition shades, are presented in the traditional manner and "dynamized" only by considering long-run population increase and long-run increase in satisfaction of wants through technological progress. Monetary and cyclical changes as well as problems of government intervention are excluded.

The author starts leisurely in the German manner to investigate *"Das Wesen der Konkurrenz"* discussing similarities and dissimilarities of competition and foot races, tracing the origin of the simile dutifully to Cicero who in turn has ascribed it to the Stoic Crysippos. The author ponders whether a comparison with horse races may not be preferable as they depend not only on the skill of the jockey but also on the financial ability to buy the right horse. Pure and perfect competition are defined in the customary manner and the static welfare maximum under competition using the Lerner criteria is shown. A rather general discussion about the relation between model and reality follows.

Maldevelopments—the main topic—are defined as endogenous economic developments which, in a competitive economy with growing population and increasing level-of-want satisfaction, interfere over the long run with the optimum satisfaction of individuals and hence with aggregate welfare. Enumerated and briefly discussed are: excessive price rigidity, excessive price flexibility, delayed cyclical price reaction (cobweb theorem), anomalous price reactions (backwards sloping supply curves); then, loose relations between price and cost, divergence between private and social revenues and costs (external economies and diseconomies), peculiarities of factor supply; finally, structural over- and underdevelopment on the fringes of the public sector and the problems of depletable natural resources and enterprises too small to employ one person fully are discussed. This is followed by some rather inconclusive remarks on income distribution, high distributive cost, and advertising. The concept of ruinous competition, on which the *Reichsgericht* based its appraisal of fairness of cartels over fifty years ago, is justly criticized.

A "realistic" (*wirklichkeitsnahe*) and "dynamic" theory of monopoly and oligopoly is attempted as best fitted to a reality shading from competition into the other market forms. Only the sellers' side is examined, though even moderate realism ought to pay attention to bilateral monopoly and its kin. Essentially, changes in cost and demand over time in regard to profit maximization are considered, though the familiar phenomenon of charging less than the full monopoly price for fear of government or intrusion of newcomers is also treated. "Competitive Monopoly," that is, monopoly which continuously lowers its prices and cost, though not necessarily total profit, is suggested as the prevalent type of industrial monopoly. The phenomenon is due largely to long-range competition from substitutes and long-range fear of newcomers. In the area of oligopoly the prevalence of compromise, not hostility, between sellers is suggested as most likely. Kinked demand curves are used to show the consequences of group discipline.

The author undertakes to analyze long-range changes through a three dimensional graphic presentation. It uses conventional money and quantity axes, and time as a third axis so as to give in depth the changes of demand and cost curves over time. This method of graphic presentation only accentuates, it seems to me, a fundamental weakness of the author's well-intentioned attempt to achieve realism by introducing changes over time. The traditional Marshallian curves do not refer to periods of real time but to partial abstractions from reality in regard to time periods under consideration by the seller. By setting up families of traditional marginal and average cost curves for different time points, not much is achieved. In the sellers' and buyers' minds, momentary short-run and long-run considerations and expectations are present in some undefinable mixture at any moment of time. This makes it impossible to add up, so to speak, simple graphs, in order to achieve greater realism.

The book is an attempt to grapple in a reasoned though hardly original way with competition in relation to the social order (welfare). Many relevant issues are surveyed. Consideration of the concept and requisites of workable competition would have put the discussion on firmer ground; J. M. Clark's classic article is quoted but not adequately considered. It must be surmised nevertheless that the book will be of value to the German reader, though it discusses matters quite familiar in this country. In the present state of the doctrine it should not be held against the author that he has not applied the refinements of modern Anglo-American welfare economics. The time-honored practice of developing *ad hoc* criteria arising from policy suggestions by students of concrete problems—has been recently recommended also by an experienced and representative practitioner of modern welfare doctrine (see M. W. Reder in B. F. Haley, ed., *A Survey of Contemporary Economics*, Vol. II, p. 36).

WALTER FROEHLICH

Marquette University

A Review of Economic Doctrines 1870-1929. By T. W. HUTCHISON. (Oxford: Oxford University Press. 1953. Pp. xiv, 456. $6.00.)

Mr. Hutchison's present work is indeed a *review* and not an exhaustive treatise. In one volume of 430 pages of text he deals with the contributions to economic science of approximately eighty persons, whose works account for the evolution that took place in economics during this sixty-year period. In most cases the contributions in question are discussed at sufficient length and penetration to convey a clear idea of the essence of their doctrines as well as a perspective on the impact of the latter on the growing corpus of economic knowledge. Yet the work of some writers who become important toward the end of the period—for instance Davenport, Pigou, J. M. Keynes, Bowley, Mitchell, and J. M. Clark—receives very hasty analysis and sometimes only passing mention. This raises a question as to the wisdom of dealing with so many economists in one volume. What the *Review* gains in scope and in

ability to exhibit the rich variety of doctrinal efflorescence that occurred has in some cases been obtained at a sacrifice of desirable intensity of treatment. Yet this may be of minor importance because he refers repeatedly to more extended analyses of most of the economists he mentions, which are now available in the doctrinal and biographical works and essays of such writers as Schumpeter, Keynes, Hayek, Homan, Viner, Marget, and others.

Hutchison's *Review* stands out from other works dealing with the same period in three respects: (i) a certain novelty of expository arrangement, (ii) the attention given, despite space limitations, to several neglected writers of surprising originality, and (iii) the excellence of its "synoptic" text-sections, which yield perspective on the main trends of doctrinal development and on the relations between the several schools of thought of this period.

The *Review* is divided into three parts. Part I, "The Architects of Equilibrium Economics and Their Main Critics," is arranged by individual economists and schools; it occupies about two-thirds of the volume. Here Jevons, Sidgwick, Marshall, Wicksteed, Edgeworth, Hobson, Menger, Wieser, Böhm-Bawerk, Walras, and Pareto receive a chapter apiece. Mangoldt, Schmoller, Wicksell, Cassel, J. B. Clark, Veblen, Newcomb, and Fisher get about half a chapter each, and smaller sections are devoted to Roscher, Knies, Launhardt, Auspitz, Lieben, and Schumpeter. Both Part II, "From 'Static' to 'Dynamic' Analysis," and Part III, "The Economics of Instability and Disturbance" are arranged by topics. Part II records the exegesis Marshallian and Walrasian equilibrium economics underwent in the course of critical scrutiny. The separate chapters are on welfare economics; micro-economics; profits and uncertainty; and interest, money, and macro-economics. Part III has chapters on "Crises and Cycles: before 1900," "Crises and Cycles: from 1900," and "Economists and the Problem of Unemployment in Great Britain, 1885-1929." Parts II and III unavoidably overlap somewhat with Part I because some of the ideas of writers dealt with in Part I are here repeated in summary form and placed in juxtaposition with theories of many additional writers on the topics in question. However, students may find this partial repetition helpful.

Reserving comment on Part I for the moment, this reviewer finds that Parts II and III go over ground that should or will be familiar to students after exposure to chapters on similar subjects in such sources as Stigler's *Production and Distribution Theories*, the American Economic Association volumes *Survey of Contemporary Economics*, Hansen's *Monetary Theory and Fiscal Policy*, his *Business Cycles and National Income*, etc. The advantages of Hutchison's treatment compared with those of the foregoing sources are its greater compactness and the fact that he surveys the work of more writers in tracing each of his topics back to J. S. Mill or beyond and forward into the early 1930's.

In Part I, Hutchison's treatment of his British forebears is generally well balanced and interesting. His discussion of Marshall's work on money, however, leaves something to be desired because it is not clearly linked up with subsequent monetary theory, almost as if Marshall's efforts in this realm

exerted little or no influence on his contemporaries and students. To be sure, in the proper places it is shown that Pigou, Robertson, Keynes, and Hawtrey, etc., were nurtured on Marshallian notions about money. But in the case of Keynes and his *Treatise on Money,* it is also shown—and something similar is implied in the other cases—that he had to break through Marshall's preoccupation with currency reform and turn to Wicksell and others to come to grips with monetary theory proper. This raises the question whether any outstanding economist carried on more directly in Marshall's footsteps. Of course, at least one did, namely Irving Fisher, who acknowledged that his "compensated dollar" proposal for stabilizing prices was an outgrowth of Marshallian ideas by saying that: "the proposal which is here tentatively suggested . . . involves a combination of the tabular standard with the principles of the gold standard" (*The Purchasing Power of Money,* 1922 ed., p. 337). Yet Hutchison ignores this and leaves the reader with the impression (pp. 270; 274; 334-35) that Fisher's monetary work derived from the treatise on "The Societary Circulation" in Newcomb's *Principles*. To be sure there was a strong link between Fisher and Newcomb in the analysis of the quantity theory and in their equations of exchange, but the reviewer submits that there was probably as close a doctrinal link between Fisher and Marshall in matters of monetary policy and reform.

Hutchison's chapters on the Austrians are excellent and comparable with his adept treatment of the British. His fine performance on two schools of such different orientation especially towards economic policy leads one to expect him to explain this difference and to trace it back to its doctrinal origins in Menger's elaborate conception of "the nature of goods" as distinct from that of "claims." Apart from contrasting the value theories of Jevons and Menger, this problem is largely ignored. One can only suggest here that Menger's "goods"-doctrine, which tended to exclude "claims" from economic analysis, was adopted by Böhm-Bawerk, and was later carried over from Austrian capital theory to monetary and fiscal analysis where it hampered progress by basing the latter on barter-economy postulates.

Hutchison's characterization of Wicksell's capital theory—originally a reconstruction of that of Böhm-Bawerk—as ". . . ingenuity . . . largely wasted . . . [on] a blind alley" (p. 234), will not be taken seriously by those who have familiarized themselves with Wicksell's own, final capital-structure concept (*cf. Lectures-I,* pp. 151-65; 202-06, and Appendix 2; and also Lindahl's *Studies in the Theory of Money and Capital,* Part III, which supplements Wicksell's work). Moreover, contrary to Hutchison's impression (p. 234), Wicksell abandoned his vulnerable investment-period quantification of capital for his viable structure concept, and in 1919 he also retracted his earlier objections to Walras' formulation of capital theory (*cf. Lectures-I,* Appendix 1, pp. 236-37 and 226-27 in the order given here).

On the other hand, one can not complain about Mr. Hutchison's competent discussion of Wicksell's monetary theory, although one might wish that more of it had been centered on the later analysis in *Lectures-II* than on that of *Interest and Prices.*

A real virtue of Hutchison's *Review* is that it brings out the contributions of several economists whose works rarely receive mention, to say nothing of the attention they apparently deserve, in standard texts on economic doctrines. As if to make up for this neglect, the author has devoted many hard-to-spare pages to such neglected German and Austrian writers as Mangoldt, Schäffle, Launhardt, Auspitz, and Lieben; to Americans such as Newcomb, Hawley, Crocker, and Johannsen, and to Englishmen such as Sidgwick and Foxwell.

It will probably surprise most readers, as it did the reviewer, to find, for instance, that Mangoldt in the 1860's, when the German historical school was dominant, was a theorist of major caliber with a value theory reminiscent of Marshall's and a monetary analysis foreshadowing that of Wicksell; that Johannsen in 1903 anticipated some of Keynes' work both in *Treatise* and in *General Theory* with his astute analysis of the impact of saving on income and employment and with his multiplier principle; that, in the 1870's and 1880's, Schäffle, Sidgwick, and Foxwell alike were groping for definite criteria for economic policies for steering a "middle course" to higher levels of general welfare by mitigating and removing the evils of unrestricted competition and stemming the greatly feared tide of socialism.

The *Review* opens with a chapter on "political Economy in England After 1870" which describes the condition of orthodox economics on the occasion of the centenary of *The Wealth of Nations*. Few accounts of the culmination and decline of the classical school are more lucid than this. Similar, shorter accounts describe the state of economic thought around 1870 in Germany and Austria, in France, and in the United States.

We do not wish to bring this review to a close without paying tribute to Hutchison as a most scholarly and competent guide to the economics of 1870-1929. His writing, amply documented for the benefit of serious students, shows clearly that he has read and reflected at length on the original works of the many writers he reviews, as well as on the pertinent commentary literature that has sprung up around them through the years. This fully justifies the confidence most readers will place in his judgment when his discussion takes them into unfamiliar territory. His *Review* merits wide and serious reading mainly as an outstanding treatise, not merely "another text."

CARL G. UHR

San Francisco, California

A History of Economic Thought. By JOHN FRED BELL. (New York: Ronald Press. 1953. Pp. x, 696. $6.50.)

Professor Bell's work begins with the recognition that "there is a definite need for a volume that provides a unified approach, a manageable organization, and breadth of coverage so that the diverse materials in the history of economic thought may be more easily summarized and integrated" (p. v). In keeping with these objectives, the reader is presented with a volume of unusually broad scope; one notes in particular the completeness of the discussions of the cameralists, the minor American economists of the nineteenth

century, and the nationalists, romantics, and optimists. Unfortunately, the further pursuit of his goals is crippled by the author's reluctance to arrive at systematic generalizations—a reluctance traceable to his feeling that "it is a dangerous and somewhat unprofitable pastime to attempt to classify economists or place them in 'schools' " (p. 658). As a consequence, breadth of coverage is frequently associated with tedious and diffuse treatment, while a meticulous scholarship spends itself in tracing minutiae such as the pedigree of the phrase *laissez faire*, or the literary history of Quesnay's *Tableau*.

In its organization the work follows the conventional chronological plan, beginning with the Bible, the Greeks and Romans, and medieval thought. The emergence of modern economics is found in the mercantilists, the cameralists, and the physiocrats. The major portion of the volume is then divided into parts dealing with classical economics, the critics of classical economics, marginal utility economics, economics in the United States, and concludes with a discussion of "Main Currents of Economic Thought in the Twentieth Century." The central focus around which the evolution of thought is built consists of a thorough treatment of Marshall's *Principles*, from which stems much of the author's position as to the nature and rôle of economics. Yet even here one could ask for a more complete recognition of the limitations of Marshall, especially in the light of recent developments in both aggregative and dynamic economics. Closely related is the social outlook that colors much of the book. Bell asserts that, while capitalism is wasteful, and is characterized by periods of unemployment, "regrettable as this is, it seems preferable to complete surrender to government . . ." (p. 662). This seems a rather overdrawn picture of the alternatives to place before the student.

From a pedagogical standpoint the book, in spite of its encyclopedic character, suffers both from the author's cramped style and the diffuseness of treatment to which his method condemns him. Furthermore, one must note a prevalence of doubtful interpretations and statements of fact, both in the tracing of ideas and in their historical setting. We are informed, for example, that by the last quarter of the eighteenth century "the corporation as a form of doing business . . . was firmly established" (p. 149). The meaning and significance of classical economics is blurred by the author's view that "the economics of Adam Smith and the classical group was largely objective or exchange economics of the market place" (p. 9). On this basis he contrasts the classicists, assumed to be interested primarily in price, with the marginalists, who instead are concerned with value as such. This misconception of the rôle of value in classical economics is broadened into the time-worn comparison of the labor-command and embodied-labor theories of value in the works of Smith, Ricardo, and Malthus, with no clear reference to the contexts in which the theories are used and without which the distinction cannot be illuminated for the student. Marx is dismissed as having "added little or nothing to the broad development of economic thought" (p. 656); presumably the concern of Joan Robinson, Domar and others with Marx is misplaced. In his discussion of Keynes, Bell becomes involved in a confusion as to the

nature of technical "macro-economics," which he first relegates to the abstract status of "a sort of general equilibrium concept," yet almost in the same breath accuses of regarding *laissez faire* as "a completely untrustworthy philosophy" (p. 601). More specifically, "those who went overboard in embracing Keynesian doctrines without qualifications" are charitably invited "to return to the fold of price theorists" (p. 658). One wonders how many would be surprised to find that they had ever left the "fold." Certainly Keynes himself did not regard the *General Theory* as a replacement for price theory.

ROBERT CAMPBELL

The University of Oregon

Fundamentals of Political Economy. By DEAN A. WORCESTER, JR. (New York: Ronald Press. 1953. Pp. xv, 594. $4.50.)

Professor Worcester has written an introductory text for a one-semester course in economics that stresses problems and policy. Believing that "more economics can be absorbed in an introductory course if it begins with what the students already know and are interested in and then works toward unfamiliar and, therefore, unappreciated areas" (p. iii), he has tried to save the unwary student from the pitfalls of rigorous analysis.

The book is divided into five parts. Part I establishes the functions that any economy must discharge and examines them briefly in the context of (1) a centrally administered economy and (2) a market economy. Part II considers the problem of efficient production and contains chapters dealing with the measurement and distribution of income, the effects of government and trade unions on the creation of income, and the utilization of natural resources. Part III is concerned with the problem of stable prices and full employment. Here the author treats international trade, money and banking, fiscal policy, and the business cycle. Part IV is devoted to industrial organization, monopoly, and governmental regulation of business and labor. In Part V the text is concluded with a discussion of progress in terms of population changes and the quest for security.

Students who read this text will brush up against numerous vital and challenging issues: the threat of central planning to democratic values, the comparative merits of private and public health insurance schemes, the problem of price and profit control, the adequacy of governmental policy with respect to the maintenance of full employment, the effect of large-scale industry on the enterprise system, to name but a few. This reviewer has little doubt that the text will quicken the interest of students in these and similar issues, but he is not quite so sure that they will have acquired a sound basis for understanding them. The author has deliberately eschewed a systematic analysis which might have been used to probe the problems he raises. Instead he has chosen to introduce theoretical concepts when he has felt that "what the students already know" is inadequate. Thus in the chapter on Functional Income Distribution, Worcester has felt constrained to introduce the marginal productivity

theory of wages. The theory is illustrated by a neat and simple numerical example, but the blow is still a heavy one. The students have not been prepared in the previous chapters by an explicit treatment of marginalism. Again, in the chapter on Fiscal Policy and Business Activity he has found it appropriate to develop income analysis briefly—the equation of exchange which previously he had been relying upon apparently being inadequate for the issues at point. But in this brief treatment he explains the equilibrium level of income in terms of the equality of planned savings and planned investment, which necessarily involves him in an explanation of the discrepancies in savings and investment, *ex post* and *ex ante*. These concepts are not objectionable—the point is that the student comes upon this obstacle without warning and without having been conditioned to surmount it.

Not only does the piecemeal introduction of theory make it difficult for the student to grasp theory when he does encounter it in the text, but it sometimes leads the author to discuss problems for which there has been inadequate preparation. For example, this reviewer doubts whether the following statement about monopoly will have much meaning to the student who is not acquainted with price theory: "They find monopolies directing resources from more valuable uses into less important uses and holding them there, thus frustrating many consumer wants and making the economic system less flexible and adaptable to changing conditions" (p. 487). Later, in a discussion of the agricultural problem the author refers to the demand for food as being inelastic (p. 546), but there has been no previous discussion of price or income elasticity.

The great virtue of the text is that it is interesting. This is no mean achievement in a day when the typical text has remarkable powers of inducing sleep. Throughout the book Worcester has carried over the theme of Part I and has compared some of the organizational features of the American economy with socialist economic organization. Although this sometimes establishes in the reader's mind an unreal dichotomy between American capitalism and other forms of economic organization, it imparts to the book a freshness of outlook that is most welcome.

Instructors may well find that in the classroom they have to use considerable economic analysis, both price and income, to explain the issues raised in the text. It is to be hoped that in any future revision Worcester will develop a systematic analytical foundation that is suitable for the beginning student. His objectives are excellent. He deplores the tendency of introductory courses to ape the graduate theory sequence. Economists would be grateful if Worcester would solve the continuing and apparently ineluctable problem of the principles course—how to present systematic economic analysis to the student without driving him in despair to the history department.

Northwestern University

Economic History; National Economies; Economic Development

Economic Aspects of the Second Bank of the United States. By WALTER BUCKINGHAM SMITH. (Cambridge: Harvard University Press. 1953. Pp. 314. $5.00.)

Here is a good study, in which the author may take satisfaction; for which the Committee on Research in Economic History, to the extent of its aid, is to be thanked; and from which readers will get pleasure and profit. Since Catterall wrote fifty years ago, and Dewey more than forty, additional weathering has raised the grain, as it were, of the 'twenties and 'thirties of the last century. At least Professor Smith by his diligent and far-flung inquiries has restored the doings of the Second Bank, and what was done to it, in the whole of its life—from injudicious beginning to stern rescue, serviceable performance, political demolition, and brief, unhappy reincarnation under Pennsylvania auspices. Careful, competent scrutiny has done more than restore the texture of the times, for the fact is that only in the retrospect of more than a century do we discover the meaning of a scene which was confused to the impassioned participants.

We knew the politics of the Bank and of its assailants; we had much of the administrative modes and motives of the institution as contrasted with the ignorance and prejudice of its enemies in states and in national capital. The present author, in re-examining these, has set them against the background of American and international economic developments to give us three dimensions instead of two. Full particulars are furnished along with a talent for summary and a praiseworthy temerity in offering conclusions. It is extraordinary how many times this history supplies comment on subsequent economic and political happenings in our country. The early 'thirties of the last century were a "new era" much like the 'twenties of our own memory. Biddle and his brethren, to their critics, were conspirators under foreign domination, though not precisely in the fashion alleged against architects of New Deal and Fair Deal.

After the Revolution, putting aside the interval of the Confederation, national authority was indispensable. Its uses were questioned, to be sure, but for a decade and more the ends justified the means. Even the Jeffersonians practiced a hold-over Federalism which they could not preach. But by the period of the gentry with whom Smith deals, national power was invoked without discernment. Public virtue, to Jackson and his partisans, must take the form of public violence. Nor were their opponents in the Bank free of this disability. A beneficial blend of individual advantage with national interest was beyond the Democracy of that day. The Treasury was custodial, not creative. Biddle was economically adept, politically unskillful; Jackson was the reverse. The best to be expected was a counterpoise, not a cooperation, of forces. The country extended itself too far and too fast for self-discipline to keep pace. The economy broke down in 1837 and the Constitution was not long behind it.

This book is more than the story of the Second Bank of the United States. It lifts the curtain on the rehearsal for the Civil War. Not that the author

anticipates. The reader has to do that for himself, which makes the work, in its connotations, a valuable aid to understanding American history.

BROADUS MITCHELL

Rutgers University

Economic History of Modern Europe. By HEINRICH E. FRIEDLAENDER and JACOB OSER. (New York: Prentice-Hall. 1953. Pp. xxiv, 611. $6.00.)

Economic History of Modern Europe attempts to present the development of Europe's present-day economic system by surveying the progress made in selected countries. England receives by far the greatest amount of attention, followed by France and Germany. The authors have realized full well the impossibility of presenting a detailed study of the economic developments in all European countries in a volume designed to be used in a one-semester course. It is for that reason that they limit, for the most part, their study to the major western European countries.

The development of Russia receives far too little attention, at least to the mind of the reviewer. Although some major developments in Russia are considered, there is no detailed discussion of the development of this area of Europe. For example, the first five-year plan is no more than surveyed. The remaining Russian five-year plans are not considered, although they certainly portray the changing pattern of Russian development. The turning of Russia to the East and the industrialization of that area is not considered. True, the authors seek to emphasize the western areas, but they have not touched the changed direction and pattern of Russion growth which have caused many changes in the pattern of western development.

In tracing the development of the economy of Europe the study stresses the growth of the capitalistic system. The first section deals with the development of capitalism before 1870; the second, with "a period of mature capitalism that spanned the years 1870-1914" (p. viii); the years after 1914 have been divided according to the two World Wars with the divisions made because "We feel that 'before 1914' and 'after 1919' and 'before 1939' and 'after 1939' are major historical dividing lines like 'before and after the deluge' " (p. viii). The treatment of the several divisions is about equal in length except for the fourth division covering the period from 1939 to the present. This very important section is allocated only some 60 pages. Some advertising of this text has emphasized the case studies of the Marshall and Schuman Plans, yet these plans are only briefly covered with some four pages devoted to each. Again, much has been said about the inclusion of some 130 biographical vignettes on inventors, leaders of industry, and others who have influenced economic development in nations. Some of the sketches are noteworthy; but it is difficult to establish a justification for all, especially when there is so much important material that needs to be covered in a text dealing with European economic development.

Realizing the difficulty of presenting the economic as separate from the political, the authors have tried to interconnect the two by including a summary of the important political happenings in the beginning chapter for each

section. These summaries aid those with some background of political history but seem only to leave others with a very hazy picture of political activity during the period in question.

All major divisions of the economic development of nations are studied, with the emphasis upon agriculture, industry, commerce, transportation and communication, money and banking, and labor organization. These same topics are treated in each chronological division. The development is by countries with the major countries receiving the greatest attention. Where one or more of the smaller countries contributed or advanced a new concept, then that concept is developed. The smaller countries are not included in the main theme of the study but woven in to complete the picture.

Although the chronological periods are slightly different from those usually found in texts of this nature, the material is, of course, much the same. The authors have relied quite heavily upon secondary sources and have contributed little that is original to the study of the economic history of Europe. A bibliography is included at the end of each chapter.

For those desiring a survey text on European economic history with some background political material included, this text may be the answer. It seems best suited to the sophomore level with the instructor supplementing the text material.

John W. Chisholm

Louisiana State University

The Origins and Development of the American Economy. By E. A. J. Johnson and H. E. Krooss. (New York: Prentice Hall. 1953. Pp. x, 420. $3.75.)

This is an extension of Professor Johnson's *Some Origins of the Modern Economic World* (1936). Readers of the earlier work will find it reappearing largely unchanged as Part I of the present work (reviewed in September 1936 by N. S. B. Gras for this *Review,* XXVI, 511).

Major interest now is with Part II, *The Development of the American Economy,* which Professor Krooss has added. This part, roughly the final two-thirds of the book, tells of "the great, benevolent potential of the American economic system" and of how it happened that the American people "have a higher standard of living than that of any other nation." The publishers offer the book in its present form with the hope that it may prove useful as a supplementary text in introductory economics courses. Johnson's earlier work has already demonstrated its usefulness as a simple, clear exposition of the way in which the modern economic world came to be. His method is clearly historical. Kroos considers in greater detail the American phase of this broader development. His method is professedly historical, though the historian might prefer to call it statistical.

Certainly statistical data are present in great profusion—data on national income, per capita income, manufacturing profits from 1817 to 1826, the character of corporation investment in 1950, real wages and money wages 1929-1950, the changing composition of the labor force from 1890-1929, relative farm prices 1860-1950, etc. A complete list would be half as long as the book.

Instructors and some students will find this information useful. However, Krooss may have overestimated the beginning student's tolerance for statistics.

On the other hand, the data offered on some specific matters is sometimes so meager that it may leave the economist, the historian, and even an occasional student wondering just how conclusions in these matters are reached. In part this is due to the almost complete lack of documentation. In greater part it is due to an occasional lack of internal coherence. For instance, his generalization that real wages increased 70 per cent from 1929 to 1950 can hardly be derived from the accompanying figures on weekly and hourly money earnings even when the former, re-expressed in terms of a 1951 dollar, are seen to rise from \$50 to \$65 and the latter from \$1.14 to \$1.60 (p. 236). One wonders too what kind of dollars are involved in his \$180 billion national income for 1950 and whether a per capita increase in income from \$612 in the period 1919-1928 to \$1,200 in 1950 is an accurate measure of "improvement in living standards" (p. 167). Possibly the most misleading use of statistics appears in his discussion of the difficulty in using machinery efficiently on the family-size farm. This, he hints strongly, has led to an enlargement of farm size until in 1945 some 2 per cent of farms included 40 per cent of all farm land (p. 267). He does not mention, and the student can hardly be expected to know, that 83.2 per cent of the land in these large farms was in pasture (*Agriculture Census*, 1945, II, p. 62) and hardly involved the use of any more machinery than a jeep, a fence, and a block of salt.

These deficiencies are perhaps inevitable in a book which attempts to measure so much in so little space. There is much here of value, particularly his data on financial institutions, the expansion of government influence, and the economics of America's wars.

LLOYD R. SORENSON

University of Oregon

Report on Financial and Physical Problems of Development in the Gold Coast. By DUDLEY SEERS and C. R. ROSS. (Accra, Gold Coast: Office of the Government Statistician. 1952. Pp. iii, 172 + 63. 5 *s*.)

This publication is the result of an investigation of building activity in the Gold Coast economy conducted by the authors in the summer of 1951. The report was prepared at the request of, and is addressed to, the Gold Coast government; and though bearing considerable interest for other readers, it should be read with this fact in mind.

The authors are anxious to stress the point that the building industry (which is of importance chiefly because of the predominant rôle it plays in the Gold Coast development plan) can only be adequately understood by first appreciating the place of the industry as one of many interdependent elements within that economy. They therefore begin with a discussion of the economy as a whole, proceed to the problems encountered by a development program, and only then occupy themselves with the characteristics and problems of the building industry itself.

There are two characteristics of the Gold Coast economy which are re-

garded as of particular significance. The first is the importance of a single export crop, cocoa; produced largely by relatively small native farmers, this one item provides from 30 to 40 per cent of the total output of the economy and about three-fourths of all exports. The second feature is the fact that the country finds itself in the almost unique position of having foreign exchange (pounds sterling) available to buy more goods than can be physically brought into the country; and this situation is likely to continue for several more years at least. The bottleneck is that existing port and transport facilities are not capable of handling increased supplies. In addition, some capital goods either cannot be purchased at all in the sterling market or can only be obtained after prolonged waiting periods due to the competing requirements of the Western defense program.

With these facts as a background, there are excellent discussions of the existing commercial organization, of the currency system, of agricultural activity and its responses to changes in price, of the organization of the building industry, of attitudes toward work in the nonagricultural sectors, and other items. The book provides a very informative picture of a backward economy and of the strains and bottlenecks encountered within it upon the initiation of a program of economic advance. The findings, it may be noted, are not always what one is led to expect by more abstract economic theorizing. For example, though labor is "cheap," "as a rough general rule mechanization justified in England is justified in the Gold Coast" (p. 103). This is so because though labor is cheap per day it is expensive per unit of output due to the actual social and economic environment within which it is employed.

Although the report is noteworthy for the realistic manner in which it deals with the Gold Coast economy, in other respects the results are less happy. The analysis is distressingly oversimplified at points; shortages pointed out in one section are on occasion forgotten in seeking solutions to problems subsequently discussed; and there is considerable repetition of a few central points. A particularly annoying example of this last is that, though the lack of sufficient port facilities is pointed out again and again, there is nowhere a discussion of the possibilities which may exist of alleviating this restraint.

In addition to the body of the report, five appendices are included. These are concerned with the construction and use of a set of national accounts for the Gold Coast economy, a study of building costs, and a discussion of various statistical data which should be collected.

Statistics and Econometrics

A Textbook of Econometrics. By LAWRENCE R. KLEIN. (Evanston and White Plains, N.Y.: Row, Peterson and Co. 1953. Pp. ix, 355. $4.50.)

There appears to have been a brisk unsatisfied demand for a textbook that could teach econometrics to, say, seniors and first-year graduate students. There is a well-known inverse Say's Law of publishing, according to which

demand creates its own supply. With a degree of confidence rare in other branches of economic forecasting one could predict that this situation would result in the appearance of several textbooks in this relatively new field. And so it has. To my mind this is easily the best of the lot. It is lucid, teachable (with the right instructor and the right class), covers a lot without trying to cover everything, and, as befits a text in econometrics, tries to pay attention to both the economic and the statistical sides of whatever it is talking about. I think it will corner the market, and deservedly.

The instructor in a course labeled Econometrics faces a major problem before he starts: what shall he assume the students already know? Of course, it doesn't really matter what he assumes; it will turn out in the end that they are completely innocent of mathematics, and have a statistical training which has stressed the deeper advantages and disadvantages of the harmonic mean; some of the students may even be there by mistake, under the impression that econometrics is a novel form of psychotherapy. Klein takes for granted that his students have been through the standard two-year calculus sequence. They are supposed to know about derivatives and integrals. On the other hand they are not supposed to know about probability, statistics, matrices and determinants. But all four of these notions come up again and again in the course of the book. Klein believes he has covered himself by including as Chapter 2, in some 40 pages, a brief summary of probability and statistical inference, and as an Appendix another 20 pages on the elementary properties of matrices and determinants. I fully sympathize with the intent of this device, but I frankly don't think it stands a chance of success. In the first place, his hasty attempt to skim here and dip there leads Klein into casual mistakes; he states on page 51 that the sample mean *always* consistently estimates the population mean, on page 57 that *all* tests of hypotheses are unbiased, and on page 61 that *all* zero-sum, two-person games are determined. But what is much more important, the plain fact is that probability, statistics, and linear algebra are deep and important fields of knowledge. The only way to learn and use their results is to study them seriously. It is idle to believe that anyone who has not done this can understand and appreciate the material in the rest of this book. Actually, only the statistics is really indispensable. The algebra can be circumvented except for the discussion of some computational techniques. But algebra is *useful*, not only here but also elsewhere in economics. A student motivated to learn econometrics ought to be willing to learn first a little mathematics and statistics.

The heart of the book is Chapter 3, which discusses the estimation of aggregative models completely and in detail. Most of the work is carried on in terms of a few particular models of the kind Klein has worked with elsewhere. Simple least squares is handled first. Then the identification problem is introduced and the maximum likelihood and limited information estimates for linear systems are explained. I know of no other place where the student can get such a clear idea of what equation-system methods are all about. In addition a few bits of extra sophistication get tossed in, such as Geary's method of instrumental variates, and the treatment of autocorrelated disturbances.

Taken together with Chapter 4 on computational design, which contains an extraordinarily meticulous treatment of the least squares (Doolittle), maximum likelihood, and limited information computations, this part of the book should equip the reader to perform, let alone understand, analyses of this type. As Klein points out, it is of first importance that students should actually perform econometric research, computations and all.

Chapter 5 is concerned with the treatment of models of the same type, only less aggregative. It is quite possible that in the present state of the art less ambitious studies of single industries or markets are more to the point than the more grandiose schemes. The treatment is again very useful, practical without being excessively mechanical, and illustrated by some of Klein's work on the railroads. The suggestions for "grafting" sector models onto aggregate models are novel and promising, a good thing for graduate students to learn.

Chapter 6 has some material on prediction, some of which is a little formal for the level on which it is pitched but otherwise a good lesson, and a section on input-output models which is much too brief to be useful. The last Chapter, 7, has three sections. One is on models which contain errors of measurement instead of the now more usual shock terms, one per equation. The discussion centers around weighted regression methods, which assume at least the ratios of the error variances to be known. Pedagogically I think this will be most useful as evidence to the student that figures never speak for themselves, and that without assumptions you get no conclusions. It would be well for the instructor to point out what Klein neglects, that with wrong assumptions you get wrong conclusions, and sometimes no warning. A second section is on weighted regressions from sample survey data. This is excellent, but much too brief. I would have liked to see it expanded into a chapter on the full treatment of sample survey data, beginning with some elementary facts about design. There is at least an even chance that here and not in time series are the more fertile fields. The final section takes up the treatment of monthly and quarterly data. I always look eagerly to see what an author has to say about seasonals. Klein comes out very well. He teaches the student only correct things, but unfortunately without bothering to explain why the "classical" methods are no good. The whole last third of the book does not quite maintain the expositional excellence of the rest; there is a noticeable lack of worked examples, for instance. But this is a minor quibble.

I feel a little more strongly about the selection of topics studied. A reader whose whole acquaintance with econometrics came from this text would think that there is nothing to the subject but various applications of linear regression and related techniques. For almost nothing else is covered. Now realistically, pride of place must certainly go to regression techniques. But for students whose outside acquaintance with statistics is meager, a more extensive and less parochial selection would have been fairer and more useful. I have already mentioned that I missed a general discussion of sample surveys. Lorenz curves are merely mentioned, and no other techniques for studying frequency distributions get even that much. The index has no entry under index numbers. This is a narrow view.

I used to think econometrics was the wave of the future; now I am not so sure. It is just possible that the fault lies not in ourselves but in our stars. In any case, where is current research effort best directed? Probably at this stage improvement of the quality of the data, and the development of richer and more realistic economic hypotheses will have higher yields than the further refinement of already top-heavy statistical methods. Even so, high precision is hardly to be expected in this business. But graduate students should be taught what econometric analysis can do; and this is the book they will learn from.

Robert M. Solow

Massachusetts Institute of Technology

Introduction to the Theory of Games. By J. C. C. McKinsey. A Rand Corporation Research Study. (New York: McGraw-Hill. 1952. Pp. x, 371. $6.50.)

This is the first text on the theory of games to appear since the publication of von Neumann and Morgenstern, *Theory of Games and Economic Behavior.* Proofs of the fundamental theorems have been simplified considerably since the latter book appeared, and, in addition, many new results have been obtained. McKinsey has incorporated these developments in his book, and has included a much higher proportion of new results than is usual for textbooks. Whenever there was a choice among methods of proof, McKinsey has chosen the more elementary methods. He seems to have done this without sacrifice of content.

For those with limited mathematical equipment who are interested in acquiring a detailed knowledge of the theory of games, this is an excellent presentation. It demands of the reader a knowledge of calculus (including the notions of convergence, continuity, derivative, integral, minima and maxima), some smattering of matrix algebra and a willingness to follow the arguments closely. The book is written with unusual care and precision, resulting in a clarity of expression for which the reader, particularly the mathematically weak one, will be grateful.

The first six chapters present the theory of zero-sum two-person games where each player has a finite number of strategies. These games are studied in both normal and extensive forms. Chapters 7 through 10 consider zero-sum two-person games where each player has infinitely many strategies. Some mathematics essential for this theory is presented here. These chapters could be omitted without loss by anyone not particularly interested in this special class of games, since all the basic ideas are developed in the chapters dealing with games involving a finite number of strategies.

The chapters on n-person games will be of particular interest to economists. McKinsey presents the von Neumann-Morgenstern theory of n-person games in a very clear way and is careful to point out its shortcomings. He also presents the Nash theory (essentially a generalization to n-person games of the notion of equilibrium originally defined by Cournot for the duopoly

problem), and discusses approaches along other lines. Those interested in following the courses of contemporary mathematical economics will find this material invaluable.

McKinsey makes some attempt (two chapters) to present the formal connections between the theory of games and linear programming, and the theory of games and statistical decision theory. These chapters will be more useful to readers already familiar with the fields.

The clarity of thought, the precision of exposition, and the completeness of coverage of this book make it an excellent introduction to the theory of games.

Business Fluctuations; Prices

Economic Change: Selected Essays in Business Cycles, National Income, and Economic Growth. By SIMON KUZNETS. (New York: W. W. Norton. 1953. Pp. viii, 333. $4.50.)

This is a collection of essays by the distinguished nominee for president of the American Economic Association in 1954. Nine of the eleven essays in this volume have been published previously (two in Spanish), but many are inaccessible to the average reader. They range in scope from almost purely theoretical to eminently empirical (although more technical and more methodological candidates for inclusion were rejected). The coverage indicated by the subtitle represents, "albeit roughly," the sequence of the author's interests.

The volume begins with two essays, dated 1930, attacking the equilibrium concept dominating the English-American tradition in economic theory in the first quarter of the present century. These throw a great deal of light upon the author's development as an economist, largely explaining his subsequent restless concern with dynamic phenomena and with inductive investigation. This provided their greatest interest to the present reviewer, for, read today, they seemed a little commonplace and awkward: much of their constructive content is today more effectively and adequately expressed in other ways. This very fact is, of course, a tribute to those, including Kuznets, who pioneered in the revolution in economics of the two decades which followed.

The third essay, also in some respects obsolete, stands the test of time much better. It is the well-known exposition and criticism of the acceleration principle: "The Relation Between Capital Goods and Finished Products in the Business Cycle" (1934). Although "interaction with the multiplier" is hinted at in a footnote, the essay otherwise considers the acceleration principle standing by itself. Nevertheless, it still deserves study and reflection. Apart from the care and completeness with which the several versions of the acceleration principle are expounded, the essay's criticisms of the principle, and its statistical tests, are very relevant for those seeking to place the accelerator at the

center of their explanation of the cycle. Hicks[1] might well have studied it with care.

What is badly needed today is a comprehensive re-evaluation of the acceleration principle, written with a scope and care comparable to Kuznets'. Until that is done, Kuznets' essay remains essential.

Following a sympathetic yet critical review of Schumpeter's *Business Cycles*, treatment of cycles concludes with a hitherto unpublished essay on "Economic Trends and Business Cycles" (1947), an essentially speculative discussion inspired by Wesley Mitchell's characterization of business cycles as the product of a business enterprise economy. In it Kuznets reveals his identification with the Mitchell concept of the cycle as a congeries of related movements in separable activities—a "unity in diversity." He also reflects the essential reluctance of this school to consider macro-economic relationships. Nevertheless, the essay sparkles with hypotheses for the interpretation of economic history—both trends and cycles.

The sixth essay considers problems of national income comparisons between "industrial" and "pre-industrial" nations. It is an example of Professor Kuznets at his best, full of profound and illuminating appreciation of the nature of economic activity and the problems of its measurement. At once imaginative and practical, it exemplifies the pragmatic ingenuity which pioneered the "invention" of national income accounting, an invention which one writer has characterized as more significant (to victory in the recent war) than that of atomic energy.[2] The major conclusion of the essay, incidentally, is that international comparisons of the sort made by Colin Clark grossly overstate the differences between the per capita national incomes of such countries as the United States and China.

In the course of reaching this conclusion, the author raises very serious doubts in his reader's mind as to the meaning of national income *as a measure of economic welfare*. These doubts are further expanded in the closely related essay which follows, "National Income and Economic Welfare." But, with characteristic optimism, Kuznets concludes only that the current development of national income and product measures needs to be expanded in new dimensions and directions. Unfortunately, most of these new dimensions are ones in which sociological and psychological considerations, and even value judgments, increasingly enter.

The preoccupation with social and cultural factors becomes even more marked in the next and most recent essay, "International Differences in Income Levels (Reflections on Their Causes)" (1950). Here Kuznets considers and successively rejects, as the primary explanation of these differences, population growth, industrial structure, literacy, investment per worker, climate

[1] J. R. Hicks, *A Contribution to the Theory of the Trade Cycle* (Oxford, 1950). To be sure, Hicks' treatment recognizes, and embodies, many of the limitations suggested by Kuznets, including one very significant one which Kuznets fails to consider—the lag between investment decisions and the production of capital goods. The latter, of course, becomes particularly relevant only when the multiplier is thrown into the pot with the accelerator.

[2] J. K. Galbraith, *American Capitalism, The Concept of Countervailing Power* (Boston, 1952), pp. 79-80.

and natural resources, racial characteristics, and national size. Instead, these differences can only be understood in terms of processes of historical development, a development which has required in the industrial countries—and will require in the yet undeveloped countries—a revolution in individual and social attitudes, cultural values, and structures of power.

The further study of economic growth will require intensive development and exploitation of quantitative data. "But the inquiry cannot, and should not, be limited to quantitative data alone. . . . The historical heritage of the several countries as embodied in patterns and values dominating social behavior, their political structure, their attempts, successful and otherwise, to adapt the elements of the industrial system to conditions within their boundaries, would have to be examined. . . . A proper analysis of data of this kind, in conjunction with quantitative data, would impose upon the scholar problems for which the tools of his particular discipline—whether it be economics, political science, sociology, anthropology, statistics—may not be adequate."

The development and broadening of Kuznets' thought over twenty years is at once apparent when we turn to the essay which follows: "Retardation of industrial Growth" (1929). Here Kuznets is considering, in part, the very problem discussed in the previous essay. But social, political, cultural factors barely intrude. Growth is measured statistically. Its explanation lies primarily in technological factors and in "economic conditions in their technical aspect."

The volume closes with two more recent essays. One, written on the eve of war in 1941, speculates as to postwar trends in economic growth. The other, written since the war, reviews in lucid fashion the past trends in U. S. international economic relations, and their possible future directions. From the former we pick up two sentences with which to characterize the author of these essays. "There is no one as revolutionary as a scientist within the narrow field of his specialty, and no one potentially as conservative in the broader field that provides the basic postulates for his specialty." From the earliest to the latest of these essays, the constant challenge which Kuznets has posed to complacent acceptance of established postulates not only in his own field but in all to which it is related displays the exception which proves his rule.

His own work has increasingly exemplified the need of which he speaks: "In the social sciences we have need of a new group of workers who combine the mastery of detailed careful procedures essential to the research scientist with the wider horizon of the historian and social philosopher, and we have need on the part of our specialist groups of greater awareness of the variety of historical experience and mutability of the social framework within which lie the more narrowly defined phenomena that they study."

GARDNER ACKLEY

Economics in the Public Service. The Intimate Story of the First Six Years of the Employment Act. By E. G. NOURSE. (New York: Harcourt, Brace & Co. 1953. Pp. xi, 511. $6.00.)

This volume is an account of a noble, controversial and surprisingly difficult experiment in the organizing of government for integrated economic

functioning; as seen by one who was a principal participant during the first half of the period covered, and an interested observer during the second half, after his resignation as chairman of the President's Council of Economic Advisers. In Nourse's account, substantive matters of economic policy take second place to the administrative questions involved.

His account falls into three parts. Part I (six chapters) sets forth his philosophy of economic advisership, precedents for such advisership and the developments culminating in the Employment Act—this last feature being completed by Chapter 17, on the intent of Congress in passing the Act. Part II (ten chapters) is a factual narrative of the application of the Act, as objective as the author can make it (but his critical judgments refuse to be wholly concealed). Part III (five chapters) presents his reflections and appraisals, first retracing parts of the narrative in a less objective mood. The book is a mine of information as to the detailed working of this experiment, and an impressive object-lesson in the complications involved, especially in the attempt to utilize professional economic analysis and advice.

First as to the intent behind the Act. There were disagreements over the defining of the objective, and the specifying of compensatory spending as a means. These were resolved by substituting more general for more specific mandates; hence the omissions are peculiarly instructive. The phrase "full employment" was rejected and the word "opportunity" inserted, together with expressions intended to exclude employment of the "leaf-raking" type. Rejected was the explicit concentration on compensatory spending. In practice, so far, fiscal policy has bulked large, but as a means of limiting inflationary pressure rather than remedying insufficient employment, with the result that it appears in a conservative, rather than a radical, rôle.

Eliminated in Conference was a requirement that the Council make available to the Joint Committee all the "studies, reports and recommendations" which it has submitted to the President. This requirement would have made confidential advice by Council to President impossible; but its elimination left the question open, so long as the Council might be called to testify before the Joint Committee.

Omitted also was the proposal that the members of the Council represent different groups in the economy. But the principle, for which Nourse has contended, of bringing "scientific" economics into the picture at the Council level, and of permitting its members to retain an independent and objective professional character, was not actually written into the Act, and was not the intent of all its supporters. The placing of professional economists on the Council stemmed from the inherent logic of its task, not from the clear intent of Congress. This issue of professional objectivity was, of course, the main point on which Nourse split with his two colleagues on the Council, and his attitude begins to show in his opening chapters. He distinguishes economic science and economic engineering. The former, though inexact, may detect and measure departures of actual conditions from an optimum; but devising remedies is a task of engineering or practical policy. Nourse extends the

concept of engineering to the *economic aspect* of the work of the politician, recognizing that he is in addition a leader or salesman, demagogue or statesman or a little of both, and mediator between what is good economic engineering and what will be accepted by the citizens. Nourse says: "Broadly speaking, I think we should have economic scientists in the Council posts and in the staffs of both Council and (joint) committee, economic engineers (of varying degrees of professional competence) in the person of the President and members of the Joint Committee, the real formulators of national policy." To the reviewer, this does not seem fully to fit the fact that the Council, in addition to scientific analyses, is called on to give policy advice, on the level of economic engineering, to politicians who may legitimately overrule or modify it in the light of other considerations pertinent to their more inclusive task. The resulting dilemma seems to have been the real trouble-breeder, ramifying out into a complex of other questions.

Nourse's answer is uncompromising, centering in the statement (p. 417) "The moment a man accepts the President's invitation to become an Economic Adviser (or White House aide), he must either take on a confidential status or become a liability to his chief." This calls for truly great self-abnegation. An economist of high standing must forgo the published work which is the means to further recognition, without receiving in return any assurance that he will have contributed directly to policy decisions, asking merely that his advice shall have been considered before policy decisions are made (Truman, Nourse felt, did not give it such consideration). Even his service of public education would be placed under added limitations which might be rather severe. For such a man, this sounds likely to mean martyrdom, anonymous.

Nourse proposes that the Council issue no separate report of its own, merely appendices to the President's report (for which it will still, presumably, have furnished raw material, coordinated in the light of prior liaison with interested departments and agencies). The Council could also hold conferences with groups outside government, and its members could even give public addresses on safe subjects. Nourse attempts no answer to the question who should sponsor, in Congress, on behalf of the President, a program more comprehensive in scope than any executive department, and presented to an equally comprehensive Joint Congressional Committee. And, to the reviewer, this almost anonymous status appears incompatible with the original idea of Cabinet status and prestige for the Council. Its effectiveness appears to depend on finding out how much economic analysis the President will have time and capacity to assimilate, and giving it to him in corresponding doses (necessarily summaries) while at the same time briefing with more extended analysis the personal advisers (if identifiable) to whom the President will turn for guidance in deciding what weight to give the Council's economic engineering as against broader political considerations.

The antithesis of this anonymous advisership would be the concept of a political ministry without portfolio, charged with developing coordinated policy, which should be economically sound and should fulfill the mandate of the

Act, always subject to the President's approval. They would presumably support, before Congress, a presidential program with which they did not agree 100 per cent, but serious disagreement would call for their resignations. On either basis, Nourse makes it clear that numerous practical problems remain. It is perhaps not surprising that these were not fully foreseen in the setting up of this novel governmental mechanism. But it is taking time to work them out, and in the meantime they can threaten the success of the experiment. They will be points to watch in the fresh start which the new administration has undertaken to make.

Turning from the Council to the Joint Committee, it is not faced with the self-effacement of a confidential adviser, but its members must limit their direct legislative activities, to spend time on an advisory function which has not fully proved its importance (though Nourse cites cases in which he thinks it has been effective). Able and outstanding members have spent a notable amount of time on the Committee's work, and have advanced somewhat beyond the stage of dividing on straight party lines. But problems remain.

In Nourse's final appraisal, the conclusion is that all four main features of the Act—the declaration of national policy, the President's Economic Report, the Council and the Joint Committee—represent steps in the evolution of our governmental structure and function, which will not simply be reversed. Of the four, perhaps the President's Council is on the most insecure basis, for reasons already indicated. Relative to the basic purposes of the Act, the Council's economic philosophy has never been clearly formulated (*cf.* pp. 423-24). The Council has impliedly asked the readers of its reports (of which Nourse gives samples) to have faith that behind its diagnoses lies more definite knowledge than it has chosen to disclose as to what market adjustments are good or bad, and whether good market adjustments are in themselves sufficient to the purposes of the Act. And in the commendation or exhortation addressed to private interests, there is a similar implied faith that these interests know enough to choose socially good and sufficient policies. The reviewer cannot avoid having some faith of the sorts indicated—for instance, that Nourse had definite ideas about the effects of the "Brannan Plan," to which he could not get Truman to listen. But on broader macroeconomic questions, not all doubts are put to rest.

The organization of this book does not make it easy for the reader to distill from it the story Nourse is telling. Part II is divided into subperiods, each treated from the standpoint of the Council, and again from that of the Joint Committee, while Part III retraces part of the story. The result is an effect of repeated flashbacks, confusing the chronology for readers who do not have it so firmly fixed in mind as Nourse himself does. The treatment of particular problems is split into separate pieces, and some bits seem to be lost—for one conspicuous example, the enactment of post-Korea anti-inflation controls, which seem to have bypassed the whole mechanism Nourse is discussing. Is this mechanism so ponderous and time-consuming that any need for prompt action must be met by bypassing it? This is one final question with which the reviewer is left.

In conclusion, Nourse has made an enlightening contribution to American political-economic history. It is to be construed in the light of his known views. He is sure that, on the key points, he was right and those who disagreed with him were wrong. And he has furnished evidence which persons who wish to understand this important experiment cannot afford to ignore.

J. M. CLARK

Columbia University

La fin de l'inflation. By JEAN GABILLARD. (Paris: Sedes [Société d'Édition d'Enseignement Supérieur]. 1952. Pp. xxxvi, 359.)

Why and how do inflations end? This is a neglected aspect of economic study. Most theoretical treatments of open inflation view it as a cumulative process, proceeding indefinitely until brought under control by forces outside the private economy—credit restriction, currency reform, price and wage control, etc. M. Gabillard's dissertation breaks with this convention. Impressively erudite, and drawing freely on both theoretical and descriptive literature in three languages, Gabillard treats inflations as special cases of cyclical boom, generating stability or deflation in much the same way as cyclical booms are believed to generate crises or depressions. In support of this thesis, he limits himself to places and times for which reliable figures are available. His examples, four in number, are the United States in 1920, Germany in 1923, France in 1926, and once again the United States in 1948, but there are frequent references to parallel episodes in the smaller nations of Western and Central Europe. These four cases of course vary widely among themselves—in severity, in interconnection with balance-of-payments problems, in methods of eventual control, and in degree of subsequent deflation; Gabillard is to be commended for restraint in not forcing them into a single mold. Furthermore, since attention is focussed on individual jumps in price levels, this volume yields no light on the more important problem of *secular* inflation, in which successive jumps succeed each other with rapidity sufficient to produce a long-term upward trend.

The heart of Gabillard's thesis is Part III. Among the factors cumulating to reverse the four postwar inflations, he lists the restoration of transport, the recovery of domestic production and export capacity, the filling of "backlogs" of consumer demand and capital investment, the decline of world agricultural and raw material prices from postwar peaks, and the drawing of capital assets from current production and employment to speculation in produced goods, in gold, and in foreign exchange. Much of this is well known, but two points of novelty appealed to this reviewer. One is a theory that abnormal inelasticity of demand tends to shift from foodstuffs to durable goods and then again to speculative inventories as inflation progresses, and that the last-named shift may be used to signal the end of the inflation. The other is a theory relating the duration of inflation to the time period required for mass per capita consumption to return to its real preinflation level. As regards the *political* economy of inflation's end, Gabillard maintains that effective anti-inflationary monetary or fiscal legislation is permitted by the capitalist class only under

conservative governments, which will safeguard their war and inflation profits against effective income taxes and capital levies. Schacht in Germany and Poincaré in France emerge from this treatment as hired technicians of a class, rather than public-spirited architects of financial recovery.

Also included, although as a side issue (p. 204 f.), is an excellent brief discussion of "escalation" and its effects. Since it also illustrates certain of Gabillard's methodological positions, I venture a running quotation in home spun translation:

> The location of an inflationary process has great importance for the form of inflationary development. The problems posed by the adoption of wage and salary escalation (*l'échelle mobile des salaires*) make discussion of this sort more realistic. It is as false to say that escalation has *always* an inflationary effect as to say it has *always* a deflationary one. It all depends on the location of the dominant inflationary pressures. If these are localized in the markets for foodstuffs, escalation runs the risk of further reducing the price elasticity of the demand for food; it will then have an inflationary effect on the markets for these products and elsewhere by transmission and propagation. But if, as in present-day France, inflation is above all due to a rise of profits, which are used for speculation in gold, inventories, and foreign exchange, while supplies of consumption goods are adequate, wage increases may reduce inflationary pressure by shifting income and demand from inflationary sectors (speculation) to neutral ones (consumption goods). . . . Of course, completely generalized escalation, if conceivable, would be the surest means of creating a condition of permanent inflation. But we must stress again that it would have to relate to *all* price phenomena, including rents and public finances, and that it would have to render all payments periods homogenous, so that none could benefit from any time lags. But whenever escalation is partial, it tends to be inflationary in so far as it benefits the economic class or group which dominates the inflation, and deflationary in the contrary case.

The first section of Gabillard's book is methodological, the second historical. Neither is as closely integrated with the third, or analytical, section as it might have been. Indeed, the two parts combine to furnish a scholarly pseudosubstructure for the largely unrelated conclusions which follow. Nevertheless, they are interesting in themselves. Gabillard objects (with good reason) to both the monetary and the income theories of inflation as overaggregated, and overlooking important features of the inflationary process. He favors an approach through stages in time and through sectoral price movements, and develops a tabular and graphical structure which he applies to the four inflations under consideration. The structure and its methodology might serve as a French translation of the Burns-Mitchell-National Bureau structure of business cycle analysis, applied to the allied problem of inflation, and subject to similar criticisms. They produce imposing edifices which may lead to conclusions incommensurate in importance with the apparatus itself, or (as here) largely unrelated to the technical impedimenta.

M. Bronfenbrenner

University of Wisconsin

Business Finance; Investments and Security Markets; Insurance

Investments. By Julius Grodinsky. (New York: Ronald Press. 1953. Pp. xii, 567. $6.00.)

This volume differs from most of the recent textbooks on investment in the strength of its emphasis on the theme "that the dynamic and expansive growth of the national economy is the primary source of investment value" and "that an expanding company, in an expanding industry, in an expanding economy is the touchstone of investment success." While other authors as well as experienced investors generally recognize the underlying logic of this point of view, and in fact espouse it to varying degrees, it is fair to say they in general seem to have more reservations than Professor Grodinsky as to its successful practical application to the average investor's problems. Moreover, many of them would probably be unwilling to make, with Professor Grodinsky, the flat assumption of a continuously expanding economy subject only to temporary cyclical interruptions. The possibility of a stagnant or declining economy, with attendant social and political changes, may not appear to exist for the visible future, but a conservative investment program must at least give it some consideration. In addition, analysis should be devoted to the investment implications of the renewed monetary inflation which present fiscal theories call for should adverse economic trends develop.

The content of the book is broad. Part I discusses briefly principles and objectives and the source of economic values. Part II devotes 45 pages to "Appraisal of the Industry." This is excellent material, well presented, on the growth and decline of industries and the consequences for investors. Part III, "Appraisal of the Company" is the largest segment of the book, 196 pages. It is a well-rounded discussion of the usual factors such as competitive position, financial structure, ratios, profit margin, public regulation, and management. Special emphasis is placed on management. An interesting chapter is included on the quality of corporate income. Part IV discusses public obligations. Part V devotes 155 pages to "Money and Markets," including a good discussion of yields and price-earnings ratios. A surprising feature of this section for a text stressing the fundamental importance of long-range growth is an unusually extensive consideration of market analysis and the various analytical and forecasting services. Even the venerable Dow theory is given six pages. One chapter in this section discusses portfolio management, with much space devoted to dollar averaging and formula plans. Part VI presents two chapters on institutional investments. Each chapter is followed by questions and problems, with lists of readings.

Grodinsky's book is descriptive rather than analytical, with a wide range of comment and numerous illustrations drawn from recent experience. The material is presented in an interesting manner, although some of it seems poorly integrated. Some confusion attends shifts in the point of view, as in the chapter on U.S. government securities, which is mainly a review of recent debt management policies and is written from the point of view of the Treasury rather than the investor. Why a rather complicated two-page table analyzing

investment policies and capital ratios of country banks should be put in the middle of Chapter 1 is not clear. Neither is the reason evident for inserting a chapter on preferred stocks between one on financial structure and one on financial ratios.

Despite his primary interest in common stock investment in growth companies, the author has made a strong effort to present fairly all sides of the more controversial points of policy, and in general is successful. Some slips are inevitable. One occurs in several questionable generalizations about bank portfolio policy which give the impression that investment in long-term U.S. government bonds is generally accepted as proper for commercial banks. A minor correction in the same area is that the Treasury's recently introduced tax anticipation bills were not bought initially by the commercial banks "due to the attractive yield" but because the Treasury offered the banks a bonus through permitting them to pay for the bills with credits on their own books.

To this reviewer's taste, two weaknesses of the book as a general text appear to be an unduly brief treatment of investment programs and policies and an unduly extended consideration of stock market analysis. The former would seem to leave too much of a gap between the principles laid down and their practical application, while the latter may too firmly implant some potentially hazardous ideas. Nevertheless, the book is well written, is strong in certain important respects, and merits a place on the investor's shelf.

Public Finance

The Trend of Government Activity in the United States since 1900. By SOLOMON FABRICANT, assisted by ROBERT E. LIPSEY. (New York: National Bureau of Economic Research. 1953. Pp. xix, 267. $4.00.)

Here are the facts; interpret them as you will. With admirable objectivity and detachment, this book presents the fully documented evidence of the growth of government activity during the first half of this century. There are 28 tables and 16 charts in the main body of the book along with 39 tables in the appendices. The accompanying text, largely descriptive of the data therein presented, is appropriately limited. Although isolated individual series are of necessity based on somewhat flimsy original source data, there should be no quibbling concerning the general validity of the results. The possible margins of error are eclipsed by the sheer weight of the evidence. It may be predicted that this book rapidly will become one of the most widely cited sources for more interpretative, and less objective, discussions of the problem of governmental growth.

In spite of the rather widespread recognition of this growth, it will prove shocking to some, and revealing to all, to discover, among other things, that one out of every eight employed persons works for government compared with one out of twenty-four in 1900, that one-fifth of the nation's capital assets

are government-owned whereas only one fifteenth were so owned in 1902, and that the physical volume of goods and services purchased by government increased by more than a thousand per cent over the half-century. The author concentrates on the growth in real inputs used by government. This enables a more accurate comparison to be made between government and nongovernment activity. The growth in government expenditures, the series more frequently employed, is shown to overstate the real growth in the government's use of economic resources. The proper note of caution is not excluded, however; for many purposes the growth in real inputs, or even the growth in expenditures, tends to understate the increasing impact of government on the nation's economy.

Several of the more popularly held views concerning the growth of government activity are refuted effectively. The trend toward bigger government did not suddenly begin in the 1930's; it was well established from the beginning of the century. The car was already rolling downhill; the New Deal merely started the motor. Governments do not do many things now that they did not do in 1900; they simply do a great deal more of everything. The increase in government activity has not been exclusively at the central government level. Although the relative growth of the central government has tended to overshadow that of the subordinate units, the latter have grown substantially in absolute terms over the period.

There are some interesting speculations on the possible changes in the productivity of government. Has the increasing degree of specialization which has been made possible by larger scale operation more than offset the diseconomies of bigness and the declining hours of work? This question is tentatively answered in the affirmative, although it appears that a sharper distinction between the central and subordinate units could have been introduced.

Perhaps the most interesting chapter contains a discussion of interstate differences in state and local activity. Having forty-eight units to work with, a great deal more is done statistically with the state and local employment and expenditure data than with federal data. Interstate differences in per capita expenditure are correlated with income, urbanization, and population density, and these three factors are found to explain 70 per cent of the variance. Income is shown to exert by far the most important influence. This is, of course, what might have been expected, but the supporting evidence is useful. Income, urbanization, and density elasticities are computed for the various state and local functions. It is unfortunate that the most recent state-local financial data available in the compilation of these results were for the year 1942.

The questions which emerge from all this but which are not, indeed could not be, decisively answered are the following: Is the growth in government largely to be explained as a concomitant of the general development of the economy? Or does government follow inevitably the Wagnerian law of ever-increasing relative importance? Or does historical accident represented by the two wars account for the phenomenon? Or must the growth finally be explained by a fundamental shifting of values, by the swing of the social pendulum away

from the individualism of the nineteenth century to the new statism of the twentieth? There is much to support the economic development hypothesis which is tentatively advanced in this book. One bit of evidence is presented, however, which seems to support strongly Adolph Wagner's hypothesis. This is the rather startling fact that the performance of every major function at every level of government has increased. The mere listing of the few minor functions which have declined indicates their scarcity as well as their unimportance: booths for foot patrolmen, regulation of midwives, bounties on coyotes. Does not this suggest that there may be some sort of built-in irreversibility of public activity under representative government? If increasing government activity were largely due to economic development, would not declining sectors of the public economy have appeared?

All of the explanations for government growth are, of course, partly correct, and no one is adequate in itself. The relative importance attached to each will determine each individual's projections of the trend over the next half-century. The author of this book wisely refrains from making any specific projections of this sort.

The Federal Debt: Structure and Impact. By CHARLES CORTEZ ABBOTT. With policy recommendations by the Committee on the Federal Debt. (New York: Twentieth Century Fund. 1953. Pp. xvii, 278. $4.00.)

Professor Abbott has prepared a timely study on the federal debt—timely because the new administration has created the expectancy that something new and better in the art of debt management will be forthcoming. Abbott's study is designed more as background material than as a blueprint for debt management; the policy recommendations are supplied by a Twentieth Century Fund Committee.[1] This division of labor is not a notable success.

The main study is divided into two parts called the "Development of the Problem," and the "Analysis of the Problem." Abbott stresses the importance of the problem but neglects to explain clearly to his readers what the problem is conceived to be. In his last chapter, he gives some hints by asking the question, "Is a politically controlled money market compatible with the free market process?" (p. 188). Read in the context, Abbott's question seems to concern whether monetary controls can do their work in a setting of a large national debt. Events have already partly answered this question. A study of England's experience after World War I might also have helped. The United States is not the first country to emerge from a war with a large national debt. In any case, Abbott offers no solution; he is content to hand over the "problem" to politicians. But I have no confidence that I interpret Abbott's remarks correctly.

Part I of the study is a review of postwar experience with the federal debt

[1] The Committee consists of the following: Arthur R. Upgren, chairman, Henry H. Heiman, Neil H. Jacoby, E. B. MacNaughton, Earl B. Schwulst, Louis Stulberg, and Donald B. Woodward.

including backward glances to prewar and wartime developments. The change in the ownership of the debt, the pattern of rates, and characteristics such as maturity of various types of debt instruments are discussed on broad lines. Close attention is given to the Federal Reserve-Treasury differences after Korea with appropriate quotations from the participants. Abbott keeps his own views in the background, letting the events, where possible, speak for themselves.

Part II is a more detailed discussion of matters considered earlier. The data on the ownership of the debt are carefully presented in some detail by the classes given in the Treasury Survey of Ownership. The minimum holdings of each group are noted, and these are viewed as evidence of the firm demand for government debt by each class. Holdings in excess of these minimums are viewed as sensitive to the varying economic circumstances of debt holders.

His discussion of the effects of debt sales and retirements has the merit of being definite. Treasury repayment of Federal Reserve Bank holdings is regarded as deflationary, repayment of commercial bank holdings as deflationary or neutral, repayment of nonbank holdings as presumably neutral. Treasury sales of debt have opposite effects. In adopting this position, Abbott has illustrious company; nevertheless, the analysis seems incorrect. A repayment by the Treasury of debt held by the Reserve Banks is not deflationary; such a transaction is irrelevant to private expenditures. The Treasury has a smaller balance and the Reserve Banks have smaller assets. Treasury repayment of debt held by commercial banks is either inflationary or neutral—not deflationary. Bank excess reserves rise; hence lending power rises. Treasury repayment of debt with federal funds has exactly the same monetary effects as Federal Reserve purchases of government securities. Obviously what Abbott and others must have in mind are the joint effects of both cash surplus and an equal debt retirement or a deficit and an equal debt increase. It is of course perfectly proper to consider these effects together, but there is little justification for attributing the effects of both fiscal and debt operations to debt operations alone. Although the type of error which this procedure invites has been pointed out by Henry Simons, Abba Lerner, Charles O. Hardy, and many others, there appears to be some mental block in our officialdom as well as among financial students, including Abbott, which prevents them from recognizing the elementary fact that debt retirement is an inflationary, not a deflationary, action. Understanding of these points might raise more doubt about the view, endorsed by the Fund's Committee, that debt repayment should concentrate on bank-held debt. The theory that there is something inherently unsound in large holdings of government securities by commercial banks has yet to be demonstrated.

The final chapter consists of the Committee's analysis and recommendations. The Committee recommends budgeting for a surplus (without however advocating higher rates of tax), restoring monetary policy, lengthening debt maturities, coordinating federal lending programs, and transferring the debt from banks to other holders. Yet they acquiesce in an increase in the debt held by banks as the country grows. If inconsistencies are overlooked, many of the

recommendations seem reasonable enough; but they suffer from the lack of a clear statement of what debt management should attempt to accomplish. The Committee seems unduly complacent about the interest expense incident to higher yields; this matter is dismissed by stating that interest is "only 9 per cent of federal expenditures." But, it seems to me, the Treasury should be concerned with economizing on its interest expense. Like other actions of government, the results to be achieved need to be weighed against the costs. These results in case of debt management consist of holding down private expenditures—inducing people to hold debt instead of real things. The debt structure should be manipulated to *maximize the deflationary effect of the debt per dollar of interest payment.* Short-term debt may be too expensive a form of debt on this test even though the yield is lower than on long-term debt. One dollar of long-term bonds may do more "deflationary work" than five dollars of Treasury Bills.

We cannot let the Committee's method of estimating the federal debt go unchallenged. The size of the federal debt is computed to be approximately $505 billion (for June 1951). To obtain this formidable total, the Committee includes unexpended appropriations, Federal Reserve notes, loan guarantees, all government insurance in force, and other unusual items. The concept of debt employed is a peculiar one. The $155 billion included to cover the various insurance programs, for example, is based upon total insurance in force. On the same principle of computing liabilities, all private insurance companies are bankrupt. The present amount of the liability of the government under its life insurance programs is the amount of insurance in force only upon the assumption that all policy holders will die tomorrow. I can find no justification for including Federal Reserve notes in the debt total especially since it is recommended that this "debt" not be retired. Such misinformation about the size of the federal debt may do little harm, but it cannot be said to assist the public in forming sensible opinions about debt management and monetary policy.

The relation between a Committee and an author is a delicate matter. If the arrangement is to be a success, the author should provide some substantial ideas for his Committee to consider and the Committee should not lightly dismiss the author's findings. In the present case, the initial requirement for success is missing.

EARL R. ROLPH

National Bureau of Economic Research
New York City

Taxation and Incentive. By LADY RHYS-WILLIAMS. (New York: Oxford University Press. 1953. Pp. 188. $3.00.)

The first part of this book consists of an interpretation of British historical and institutional developments over the centuries as they have influenced the basic motivations and incentives affecting the British people. The second part consists of a detailed proposal for a revision of the British tax structure and

social insurance program designed to provide increased incentives to work and savings by a diminished emphasis on progressive taxation. The first of these two parts covers about two-thirds of the volume and is of much greater general interest to non-British readers; it will, therefore, be stressed in this review.

According to the author, the book "represents a plea for the study of the whole question of taxation and incentive and of the underlying problem of how to maintain justice to the individual at the same time as justice to the community . . ." (p. 8). This problem, in the author's judgment, is of vital importance to the British economy because of the degree to which the traditional incentives for hard work and continued saving by private individuals have been weakened or destroyed. This thesis is supported, in the first instance, by a detailed discussion of the motivations for effort affecting the British economy.

The author classifies incentives into those based on fear and those based on hope of gain. In the former category she distinguishes the fear of punishment, the fear of want (or poverty), and the fear of loss. For the mass of the working population she regards the fear of poverty as the chief incentive to labor, even in the modern welfare state. She points out, however, that "the principal aim of the present century has been to put an end to want" (p. 14), thereby weakening this incentive.

The author regards the fear of the loss of position and privileges as the real incentive affecting the more fortunate classes, those not in immediate danger of actual poverty. She points out that developments during the last generation or so have greatly weakened the power of this incentive. The possession of wealth, she claims, no longer is as highly regarded as it was in the past. The prestige of the educated person in society has also diminished, and the attainment of an education is not dependent on the wealth of the parents. In addition, medical services are available to all, and domestic help is not a prerequisite to social status. "When bishops and judges announce publicly that they have to help their wives with the washing-up, there ceases to be any social stigma attached to loss of ability to employ a domestic staff" (p. 18). All in all, "The penalties for lack of success, and equally for lack of effort to succeed, which attach to the middle classes today are thus as much reduced as those which attach to the poorer sections of the community . . ." (p. 19).

The decline in the power of these incentives based on fear has placed added importance on the incentives based on gain, if the deterioration in the desire to work hard and to save, now evident in Britain, is to be checked or reversed. Unfortunately, however, public policy in Britain has also tended to erode these incentives. "The virtual impossibility of accumulating capital, or of making large-scale provision of wealth for future generations, or even for the saver's own immediate future, without losing through taxation and inflation the greater part of the money saved is naturally the most potent of the present forms of discouragement of effort based on the desire for gain" (p. 22). These effects have been compounded by the prevailing system of rationing

scarce goods which means that the acquisition of money does not result in the early possession of goods or benefits accrued.

Partly as a means of restoring incentives and partly in order to accomplish other objectives, one of which is to improve the equity of the tax structure, the author argues for a sweeping revision of the British tax structure and the existing program of social insurance fees and benefits. She describes her proposal in the following terms (p. 128):

> It consists in a merger between the income tax and the social insurance systems, as a result of which all contributions would in future be made in the form of income tax [with proportional rates and no exemptions] payable upon all the income of the individual whether earned or unearned. In compensation for the loss of the present allowances of untaxed income there would be granted weekly cash allowances, payable to every individual, on the lines of the present children's allowances. These would be in substitution for all (or part) of the present insurance benefits.

The author would limit to the nonwelfare portions of the national budget the use of supplementary income taxation, and even for this portion of the budget she approves only grudgingly the principle of progressive taxation. She states (p. 66):

> . . . the purpose of redistributing income for social purposes is not an object with a moral validity of its own. It requires national emergency to sanction it, and it cannot, without disaster, form part of a permanent system of taxation. The robbery of one group of citizens by another, even when the State, democratically controlled by the first group, acts as its agent in carrying out the theft, remains—theft.

Space limitations preclude a more detailed summary of the author's thesis and of the rationale behind it. A critical evaluation of the volume is extremely difficult for an American reviewer not familiar with the British scene. These difficulties are increased by the fact that the author herself presents essentially a summary statement of her own views and conclusions rather than a full discussion of the factual evidence underlying these conclusions.

In general, the views expressed on work and savings incentives in Britain sound persuasive and consistent with those expressed by others. The standards of tax equity applied by the author, however, appear much more arbitrary, and probably would not be widely accepted either in this country or in Britain. Likewise, the author's excursions into side questions, such as her discussion of the international factors which affect British taxation policy, contain judgments which this reviewer believes to be of questionable validity.

Perhaps the most interesting feature of the book for American readers is the contrast between Lady Rhys-Williams' view on the British incentives and the evidence as to work and savings incentives in this country. Studies of the American scene indicate that no such deterioration has occurred as Lady Rhys-Williams believes to have taken place in Britain.

J. Keith Butters

Harvard University

The Taxation of Corporate Income in Canada. By J. RICHARDS PETRIE. (Toronto: University of Toronto Press. 1952. Pp. xviii, 380. $7.50.)

Dr. Petrie's study is one of a series of volumes on taxation in Canada, sponsored by the Canadian Tax Foundation. After an introductory chapter in which the author makes it clear that taxation, in his view, is an improper instrument for social and economic control and presents the major conclusions drawn from his analysis of the corporate income tax, there is an interesting and informative review of the history and development of the application of this tax in Canada. Succeeding chapters deal with the rationale of the taxation of corporate income, its incidence and economic effects, problems related to the treatment of business losses and the valuation of assets, and the integration of the corporate and personal income taxes. Petrie concludes with a description and evaluation of Canada's efforts to restrain inflation in part through the use of deferred depreciation of new nondefense-related private investment.

Petrie agrees with the "traditional" view that a business profits tax, since it "does not enter as a cost of production in any usual sense of the word" (p. 128), is not shifted. Unfortunately much of the supporting reasoning is based on the concept of the "marginal firm" and its rôle in the market, rather than upon marginal output. The statement made in the course of the analysis that, "If, during a given period, demand and costs remain constant, the only factor that can change price is a change in supply" (p. 126), leaves one wondering about the nature of a supply schedule that is capable of shifting independently of costs!

There is, apparently, some uneasiness in the author's mind at this point, for he suggests, quite without explicit reference to oligopoly or administered prices, that "In a strong sellers' market the tax is undoubtedly shifted in many cases" (p. 143). Thus if there is excess demand at the prevailing price, that price may rise. But it does not follow that this will occur only if the corporate income tax rate is raised; even if the rise in the tax rate is a necessary condition for the price increase, this does not necessarily constitute "shifting" in any really meaningful sense.

A wide range of topics is discussed under the heading of economic effects. These include the problem of double taxation and the effects of the corporate income tax on saving and investment, distribution of earnings, corporate financing, the choice of business organization, prices in the long run, and small business and new enterprises. Only occasionally are definitive conclusions drawn, for the data required for adequate analysis are generally not available.

There is, however, one conclusion that must be seriously questioned. Petrie cites data for the years 1938 to 1950 to "prove" that the higher the effective tax rate, the higher will be the proportion of corporate profits after taxes that will be retained (p. 162). This reviewer found the coefficient of correlation between the tax rate and the percentage of after-tax profits retained to be significant and equal to .61. But the examination of the data (p. 160) reveals that the percentage of profits retained also tends to vary closely with the *amount* of profits after taxes. The latter continued to increase as tax rates

were raised, resulting in what appears to be covariance rather than correlation between tax rates and corporate retentions. The data reveal too that while undistributed profits as a percentage of profits after taxes moved in a direction opposite to that of the tax rate for five of the thirteen years, it changed in the same direction as the amount of profits after tax in all but three of those years.

In the absence of graduated rates the problem of averaging for corporate income tax purposes is relatively simple and, in Petrie's view, should be solved by permitting a limited carry-back and, logically, unlimited carry-forward of losses. In the case of corporations whose shares are actively traded, however, there is much to be said for letting "bygones be bygones," to use Simons' phrase on this point.[1] There is always the prospect that the stockholders in profitable years may not be the ones who owned the shares when the losses were incurred, in which case one must ask what manner of equity this rough averaging achieves.

Petrie believes that methods of inventory valuation and the timing of depreciation properly belong within the jurisdiction of corporate management. Cases of fraud are, of course, the proper concern of the tax administrator, but beyond that there seems little to gain and perhaps much to be lost through the use of bureaucratically established procedures. The argument for basing depreciation charges on replacement costs is well disposed of. Those are charges which are designed solely for the purpose of enabling the historical capital cost of a depreciable asset to be amortized out of income (p. 237). Any other approach is suspect and involves spurious reasoning.

In the interests of equity Petrie is compelled to discuss integration of the corporate and personal income taxes, a problem that is particularly acute in Canada because of the absence of a tax on capital gains. The only complete and logically satisfactory plan would call for elimination of the tax on corporate income as such and the taxing to the shareholder of his aliquot portion of corporate profits. "Practical" difficulties, however, preclude total integration, in the author's view, and thus make it necessary to adopt some compromise plan. After rejecting the various well-known proposals, however, he fails to offer any specific solution, and the reader is left with the impression that a long chapter has accomplished nothing save another reviewing of the pros and cons relating to these proposals.

For the American reader familiar with the general literature on the corporate income tax the most interesting and useful part of the book is the discussion of Canadian practice in this revenue field in Chapter 2 and scatteringly throughout the book. Canada has been willing, particularly in recent years, to adopt innovations which, although they do not always appear to represent wise or equitable procedures, indicate recognition by the government of the principal shortcomings and undesirable effects of the tax and a disposition to alleviate them.

International Economics

Economic Planning for the Peace. By E. F. PENROSE. (Princeton: Princeton University Press. 1953. Pp. xiv, 384. $7.50.)

One of the unprecedented phenomena of World War II was the scale of the activity that was carried on in Washington, London, and Ottawa in preparing for the peace while the war was still in progress. Before hostilities ceased not only had the Charter of the United Nations been negotiated, but international conferences at Hot Springs, Bretton Woods and Atlantic City had launched or laid the foundations for international cooperation in the fields of agriculture, international monetary and financial affairs, and relief and rehabilitation. By the end of 1945 the proposals on world trade and employment had been put forward, the British loan had been negotiated and large numbers of blueprints existed in various stages of completion for the terms of peace treaties, the treatment of ex-enemy countries and the restoration of liberated countries. Professor Penrose's volume is an account of large segments of these activities between 1941 and early 1947 as seen from London by one who participated in many of them. Its focus is an attempt to determine why and where the effort went awry, especially why despite all the planning, "economic disaster came early in Germany and was narrowly averted in 1947 and 1948 in the rest of Europe" (p. 3).

The search for the answer to this question is the unifying thread which ties together what are otherwise two quite dissimilar parts of the study. The first half of the volume is an account of the planning that went on during the war and is concerned with the long-range plans in the fields of financial and commercial policy, food and agriculture, and commodity policy as well as with the very short-range activities in the field of relief. The second half of the study is mainly concerned with policies toward Germany in the first two post-hostilities years, followed by two chapters on the problems and policies connected with the reconstruction of Western Europe from the Anglo-American loan to the eve of the Marshall Plan. The author was intimately and continuously associated with at least some aspects of all of the facets of postwar policy planning covered in the first half of the volume; apparently his connection with the events after 1945 was less close. It is presumably for this reason that the two parts of the study differ greatly in the mode of treatment of the subject matter. The first part is largely in the nature of personal memoirs and observations whereas the latter half is a more rounded account on the basis of publicly available documents. In these circumstances it is natural that the earlier chapters should be more spotty and less satisfactory as a complete account of the development of policy. It may also be the reason why the second part of the study conforms more consistently than does the first to the impressions of one who saw most of these developments from the Washington end. Nevertheless it is the first part of the volume which, although weak in its treatment and comprehension of the substantive issues, will probably be of the greatest value to the students of postwar economic policy because of the many hitherto unpublished incidents of discussions between American and British

officials which are here recorded. When the account ventures beyond the London scene into an interpretation of contemporaneous developments in Washington the reader will want to keep in mind the author's own warning that this history still remains to be written.

It is now ten years since the first of the international conferences concluded at Hot Springs its efforts to lay the basis for a viable and expanding world economy. Clearly the early realization of the objectives, so bravely stated there and subsequently, has in large measure been frustrated. Is this because unpredictable events have overwhelmed us? Was good planning nullified by failures of execution? Or was the planning itself basically ill-conceived and misdirected? On these, as on a host of extraneous matters ranging from the use of the atomic bomb to problems of negotiating with the Russians, the author's views are expressed with vigor and frequently in highly subjective and controversial terms. The text bristles with expletives such as "extraordinary ignorance," "irresponsible," "careless," etc. In general, it is his conclusion that, especially on the American side, the failures must be ascribed to the planning and to domestic politics.

The main elements in this conclusion may be summarized as follows: (1) There was too much emphasis on the establishment of long-run expansion and equilibrium and not enough on short-run and transitional problems which might necessitate policies quite antithetical to long-run objectives. (2) It was a mistake to separate long-range from short-run functions in international organizations; for example, relief and economic aid should have been administered through the International Monetary Fund and the International Bank and the resources of these institutions made adequate for the purpose. (3) There was insufficient appreciation in Washington of the magnitude of the task of restoring economic health in Europe. (4) Planning was frustrated by perversity and stupidity in Washington, especially in the Congress. (5) With respect to Germany, malice and ill-will in the Treasury and the Pentagon delayed action and almost led to disaster.

There will undoubtedly be a large measure of agreement on many of these conclusions. There will be less agreement on the extremes to which some of these conclusions are pushed and on some of the interpretations and evidence which are supposed to support the findings. This reviewer would be inclined to dispute the second and fourth of the conclusions and particularly to doubt the correctness of many of the interpretations leading to them.

It may have been unwise to separate the needs of relief and reconstruction from longer-range functions in international institutions. Whatever the wisdom, however, the author is quite incorrect in attributing this separation principally to a process of attrition and political compromise. Here as elsewhere throughout the volume, Penrose has a propensity for attributing decisions which were unpalatable to him to the perversity of the Washington political scene, to "political considerations," and to the form of the United States government, "which gives so many opportunities for irresponsible obstruction and consistently weights the scale in favor of conservatism" (p. 46). That interdepartmental coordination left much to be desired and that the

problems of securing Congressional assent were difficult and omnipresent will be confirmed by a host of civil servants. But it should also be recognized, as the author in his impatience does not, that the American people were emotionally ill-prepared for the responsibilities that were being thrust upon them and that the remarkable aspect of the record is that so much was approved, not that some proposals had to be foregone or modified. It is also of interest that what is viewed as obstruction in the United States apparently becomes virtue abroad; one can search the volume in vain for any recognition of the difficulties created by the British government's obsession with full employment policy. Perhaps the author's impatience stems in part from his disagreement with the orientation of American planning toward a freely operating and basically private economy, whereas his own hope for the post-war was an "economic order . . . developing fitfully . . . toward greater cooperation, public control, and public enterprise . . ." (p. 101).

It is also possible to agree that there may have been errors of attempting too much precision in drafting such codes of international economic behavior as the charters of the International Trade Organization and the International Monetary Fund. Simpler and broader rules might have made the codes more flexible and workable. But the study overlooks the fact that the complicated exceptions arose in most cases not from the American side, but as concessions to get as nearly universal acceptance as possible, rather than to create exclusive clubs of a few nations. Whatever the merits of this case, one need not be driven to the author's extreme position that the ideal form of international agreement is to be found in the platitudinous resolutions of the Hot Springs Conference on Food and Agriculture. On that basis agreement is always possible but it is open to grave doubt how significant or effective such agreement is.

As indicated above, the five chapters on the disastrous effects of the Morgenthau Plan on Germany and the internal contradictions of the basic directive to the occupying forces (JCS 1067) are the most satisfactory and comprehensive portion of the volume. Even so, some of the implicit assumptions and conclusions are open to qualification. Many of the policies toward Germany which were designed to prevent that country from again becoming a threat to the peace and to insure that the occupation should not at the outset have the welfare of the German people unduly at heart as compared to the position of the populations of the neighboring liberated countries were shared by many who dissented from the vengeful motives of the Morgenthau Plan. The account seems also to be unaware of Washington studies on reparation policy as early as 1943 which were very similar to those presented by Keynes which are noted in the volume. It is also open to question whether the German policy dealt a severe blow to the willingness of the U.S.S.R. to cooperate with the United States and the United Kingdom.

The general paucity of dates in the text is likely to prove confusing to many readers since events are treated topically rather than chronologically. It will also be regretted that there is no documentation of the major part of the narrative, possibly because most of the underlying documents are still classified in government archives. Without access to documents formerly in his files, the

reviewer is reluctant to cite numerous instances of fact and of interpretation on which his memory differs from the account set down here. Many a civil servant will be bemused, however, by the information that the proposals for an international trade charter had their origins in a memorandum by James Meade in the War Cabinet Secretariat in the latter part of 1942. They may also be astonished to learn that British officials were being informed that the United States was not seriously affected by imperial preferences but that our concern lay with the adverse effect of preferential systems on small and poor countries.

In addition to its other merits, this volume will serve a most useful purpose if it should stimulate the publication of complementary studies from different points of vantage before memories grow dim, since much that was significant was never committed to official paper.

LEROY D. STINEBOWER

Manhasset, N.Y.

International Trade and Economic Development. By JACOB VINER. Lectures delivered at the National University of Brazil in 1950. (Glencoe, Ill.: The Free Press. 1952. Pp. 154. $2.75.)

The small book contains six lectures which Professor Viner gave at the Getulio Vargas Foundation of the National University of Brazil in the summer of 1950. The subjects of the lectures are, with one exception, in the field in which Professor Viner has made many lasting contributions, *i.e.*, the theory of international trade and the practice of commercial policy. The first lecture, on the classical theory of international trade and present-day problems, is in part a comparison of the world and the world of ideas in which Ricardo and his contemporaries and successors formulated their theorems, and the present where the "cosmopolitan approach" of the classics no longer applies because today the conflict of economic interest between nations is taken for granted, and because economic policy can no longer be considered without express regard for strategic or security implications. This does not, however, invalidate the findings of the classics for their time; but it does call for their "adaptation to the new circumstances if not for outright rejection." The "new circumstances" mentioned are the decline of effective competition, the growth of central planning on a national scale, the establishment of new international institutions, the disappearance of the gold standard, and the increase in trade barriers through quotas, licenses, exchange controls, etc.

The next four lectures explore some of these "new circumstances," partly to deplore their emergence, and partly to show that they are not so important as to invalidate the classical doctrines.

Thus, Chapter 2 is a strong—if not to say, ill-tempered—attack on Metzler's exposition of the "new" theory of international trade in Metzler's chapter in the *Survey of Contemporary Economics*, Vol. I, based on the contentions that (a) the efficacy of the monetary mechanism has been underrated by "the Keynesians"; and (b) "true" price elasticities of demand are not as low as some empirical investigations have suggested. Chapter 3, entitled "Gains

from Foreign Trade," elaborates on the proposition that industrialization is not identical with economic development and that high income and welfare can be derived from agricultural pursuits. The fourth lecture comments on the relationship between monetary and fiscal policies on the one hand, and balance-of-payments problems on the other. It concludes that balance-of-payment pressures are inevitable wherever national economic policies "are designed to produce or inevitably involve inflation" and that under such conditions direct trade controls are likely to be the first and last resort for dealing with balance-of-payments deficits.

Chapter 5 deals with the influence of national economic planning on commercial policy and comes to the (not very startling) conclusion that "every internal direct control which has appreciable indirect influence on the course of foreign trade tends to make necessary a related direct control in the foreign trade field." It also comments on the International Trade Organization charter and the impossibility of devising rational principles governing trade relations between controlled and free countries, on the International Monetary Fund charter and its recognition of the sovereign "right to inflate," and on the difficulty of solving—"when the world at large has ceased to engage in systematic . . . inflation"—the problem of business cycles and their international transmission. In this connection, Viner voices objections against an international code of behavior to be applicable indiscriminately to all countries, and indicates his preference for an "international employment stabilization fund endowed with large resources in national currencies, and with a mandate to use these funds in making loans on a counter-cyclical pattern."

The last chapter, entitled "The Economics of Development," first struggles with the problem of defining the concept of "underdevelopment"—somewhat unnecessarily, it seems to this reviewer—and suggests that the reduction of mass poverty be made a crucial test of the realization of economic development. (I fail to see, however, why Viner believes himself to be in disagreement on this point with "the whole body of literature in the field.") He then lists the obstacles to economic development as (a) low productivity functions—caused by an unfavorable physical environment, illiteracy and low health standards, and lack of technical education; (b) scarcity of capital caused by a low propensity to save, and the limited availability of foreign capital; (c) the hindrances to international trade; and (d) rapid population growth.

The chapter and the book conclude with the rather pessimistic observation that even with the "utmost help from these external factors which there is any reasonable ground to expect," the problem of development will not be solved unless the underdeveloped countries undertake a "sound, large-scale and persistent attack on the basic internal causes of mass poverty."

Viner's lectures are a cornucopia of pertinent observations on a host of issues, although they are somewhat loosely joined together. Nevertheless, this reviewer cannot help expressing his personal regret that Viner has missed the opportunity to make a major contribution to the "economics of development." Most of his remarks and observations are peripheral to the hard core of the practical problems of economic development as they exist nowadays. The

problem of the relationship between economic development endeavors—this sound and persistent attack on mass poverty which Viner wants—and the balance of payments can be put, I believe, very simply; given (a) an agreement that it is in the interest of the world as a whole, or, at any rate, of the free world, that the per capita income of underdeveloped countries should rise at a faster rate than that of advanced countries—in order to bring about a decrease in the difference of per capita income and welfare between countries; (b) the empirically verified, or at least verifiable, fact that the income elasticity of demand for crude materials and foodstuffs which make up the bulk of the exports of underdeveloped countries is unity or less; and (c) the equally verified, or verifiable, fact that the income elasticity of the demand for imported capital and consumer goods in underdeveloped countries is at least unity—the problem arises: what mechanism of adjustment can be made operative, and what policies should be pursued by underdeveloped countries in order to maintain (or obtain) balance-of-payments equilibrium? Is an automatic adjustment possible which will not run counter to stipulation (a)? Unfortunately, Viner did not address himself to this problem and the problems of fiscal, monetary, exchange, and commercial policies which pertain to it.

International Bank For
Reconstruction and Development

A Geometry of International Trade. By J. E. Meade. (London: George Allen and Unwin, Ltd. New York: Macmillan. 1952. Pp. 112. $5.00.)

This is the latest in a series of monographs that mark Professor Meade's progress in his resolute march through the whole realm of international trade theory and policy. So far Volume I of *The Theory of International Economic Policy* has appeared under the title *The Balance of Payments* (see this *Review*, March 1952), along with a separate Mathematical Supplement. The present work is in the field of international trade proper as defined by classical and neoclassical writers, and is in the nature of a geometrical preface to the promised Volume II of *The Theory of International Economic Policy*.

This is a book for specialists in international trade: it presumes not only some general knowledge of "offer curves and all that," but some fairly sophisticated notions of what is wrong with them.

Allowing for the discontinuity between "no trade" and "some trade," an offer curve with welfare content for a two-country, two-product world can be derived under constant or decreasing costs directly from a family of community-indifference curves. The problem is to do the same thing under increasing costs, where partial rather than complete specialization is the rule, and product quantities vary continuously along a production-opportunity relationship with every variation in trade.

Meade solves this problem with the help of a construction called the "trade-indifference curve." A "production block," representing the production possibilities in one of the trading countries, is allowed to slide along a con-

sumption-indifference curve in such a way that the production and consumption indifference curves maintain tangency, and the axes of the production-indifference curve remain parallel to the corresponding axes of the consumption-indifference map. The trade-indifference curve is traced in the adjoining quadrant by the corner, or "origin end," of the production block. There is, of course, such a trade-indifference curve for each consumption-indifference curve. The slope of the trade-indifference curve at any point is the same as the slope of the "corresponding" consumption-indifference curve at the "corresponding" point, which in turn is equal to the slope of the (tangential) production-indifference curve at the same "corresponding" point. Hence an offer curve may be derived from the trade-indifference map by rotating a price line; the locus of the points of tangency between the price lines and the trade-indifference curves will be the offer curve corresponding to the given cost and preference conditions.

Meade applies the same method, by way of digression, to derive offer curves under constant and decreasing costs, thus subsuming these as special cases. The final results do not differ from standard procedure except that, if we assume partial specialization under decreasing costs (unstable except where due to great disparity in the size of the trading nations), his method shows us some interesting possibilities of multiple equilibrium.

The purpose of the book is explicitly restricted to pure geometrical representation with no attempt to apply the geometry to the solution of economic problems. Nevertheless, the main interest of the book to many readers will lie in its use of the offer curves to represent certain trading situations which, by their very names, are at least reminiscent of major problems in international trade theory and policy. These situations include equilibrium and deficit under free trade; equilibrium under various systems of duties and subsidies; and manipulation to achieve certain welfare goals, nationalist and cosmopolitan.

In addition to its direct contribution to foreign-trade geometry Meade's book supplies a useful diagrammatic background for graduate and advanced undergraduate teaching. The undergraduate, especially, will regard the fifty-one diagrams with misgiving; but, by rigorous selection, six or eight might be chosen as minimum equipment and used with advantage in classroom work.

DONALD B. MARSH

McGill University

Instability in Export Markets of Under-Developed Countries. Study prepared by the United Nations Department of Economic Affairs. (New York: Columbia University Press. 1952. Pp. vii, 94. $1.00.)

It has long been known that underdeveloped countries, because of their heavy dependence upon the export of raw materials and upon the import of manufactured goods, are highly sensitive to fluctuations in world markets and are subject to wide swings in their terms of trade. The resulting ups and downs in their balances of payments, which tend to be aggravated by cyclical swings in the inflow of foreign capital, have not only subjected the economies

of underdeveloped countries to substantial fluctuations in incomes, but have also made it exceedingly difficult for them to maintain a steady rate of development expenditures at home.

Although this situation has been commented upon in numerous publications and official reports,[1] few, if any, systematic attempts have as yet been made to measure, in comparative fashion, the magnitude of these balance-of-payments swings. Consequently, this United Nations report fills a long-standing gap in our statistical information. Eschewing analysis or policy recommendations is almost purely statistical; but within its narrowly defined limits it is exhaustive, and will be a useful source of information for specialists in this field.

More specifically, it provides answers, and does so with painstaking thoroughness, to the following questions: How large are fluctuations in prices, volume, and proceeds of exports of underdeveloped countries, classifying these fluctuations as year-to-year, cyclical, and long-term? What is the connection between fluctuations in prices, in volume, and in proceeds? What are the relations, if any, in these countries between variations in export proceeds and capital imports?

As might be expected, the fluctuations are impressive. For 25 representative commodities the within-year price fluctuations over the last half century average close to 27 per cent, the year-to-year close to 14 per cent, the cyclical about 13 per cent per annum, and long-term about 4½ per cent per annum.

A surprising conclusion is that price fluctuations are not the major factor in the instability of export proceeds; on the whole, the volume of exports has fluctuated even more than the price, both in respect to cyclical[2] and long-term variations, averaging close to 19 per cent and 17 per cent respectively. For all types of fluctuations—year-to-year, cyclical, and long-term—export proceeds have wider swings than either those in price or volume alone, indicating that changes in volume do not offset those in price. Indeed, year-to-year fluctuations in volume are often more than twice as high as in price and, therefore, result in instability of export proceeds even when fluctuations in volume and in price are in opposite directions.

The lack of any general relation between the direction of price changes and that of volume changes arises from the grouping together of food and industrial raw materials. Once these groups are separated, we find that food changes in price and volume tend to move in opposite directions, indicating—but uncertainly, as the tendency is weak—the predominance of changes in supply as the causal factor. For industrial raw materials, however, fluctuations in price and volume generally move togther, suggesting that here changes in demand may be the important factor.

[1] Attention might be called in particular to the two well-known studies of the United Nations, *Measures for the Economic Development of Under-Developed Countries* (May 1951,) and *Measures for International Economic Stability* (November 1951).

[2] It might have been well to insert a footnote explaining why, in the trend from which cyclical deviations are measured, a seven-year moving average was used when the price and volume cycles averaged about four years. If the cycles were too irregular for a four-year moving average, might not a mathematical curve have been more suitable?

Since the purpose of the study was to investigate the ability of underdeveloped countries to obtain foreign exchange, it was necessary to obtain data on capital movements and invisible earnings. Before 1939, receipts from long-term gross capital imports averaged about 10 per cent of the value of export receipts. Over the same period invisible earnings averaged between 1 per cent and 3 per cent. In the postwar period invisible earnings increased somewhat because of tourist expenditure, but long-term international investment was generally lower. However, for the half century as a whole, not only did capital movements and invisible earnings fail to compensate for the instability of export proceeds, but they fluctuated more than three times as much as export proceeds and, as might be expected, generally fluctuated in the same direction, thereby aggravating the instability of receipts of foreign exchange.

It is only to be expected that the authors were sometimes handicapped by the absence of certain data, and to that extent they had to trim the statistics to the available material. One wonders if this situation was responsible for comparing the within-year[3] fluctuations for prices only; or for South Africa, New Zealand, and Australia being—surprisingly enough—entered as underdeveloped countries for the first time in the last chapter (which is concerned with a comparison between export proceeds and capital movements), while many of the underdeveloped countries included in previous chapters are now left out. And is it entirely responsible for a succession of tables in which the number of countries, the number of commodities, and to a lesser degree, the number of years are almost invariably different? At any rate, the utmost in attentiveness is required of the reader, whose task is made no easier by the complete absence of any visual representation.

Though it is unfair to criticize a work for not going beyond its explicit terms of inquiry, it is not irrelevant to discuss the usefulness of the inquiry in its present form. We have mentioned the specific questions this report endeavors to answer. It may be doubted, however, if many would think to ask these questions in quite so restricted a manner. The report is assuredly of value when supplemented by some additional data. Standing alone, it falls short of what is necessary to convey a complete picture. For large fluctuations in exports assume importance only as exports become a significant proportion of national income, and of this desideratum there is nothing in the report. A brief comparison, between underdeveloped and other countries, of the magnitude of the export fluctuations, and of the ratio of exports to national income, would have been a useful addition.

Another question in this connection is what is the proportion of the total crop, or of the total output of materials, which is exported by the various countries? Does the proportion exported vary according to the price: for example, will a low price induce producers of some crop to retain a larger part

[3] Within-year fluctuations are not necessarily coincident with seasonal variations. The percentage within-year fluctuation is the difference between the highest and lowest price in the year expressed as a percentage of the highest price (in this study every change is expressed as a percentage of the higher price).

for their own use or consumption, in this way alleviating the hardship occasioned by their reduced money incomes?

Of course, it may well be that in all these countries the proportion of total output exported is large and that exports are a large and constant proportion of national income, and that these facts are known to anyone having a rudimentary acquaintance with underdeveloped countries. Yet it would require little extra labor to have provided data such as these to enable the interested "outsider" to form a more balanced appreciation of the impact on these weaker economies of the strain of large fluctuations.

Though the report engages in hardly any analysis and makes no recommendations, there can be little doubt that the authors are of the opinion that fluctuations are a decided obstacle in the development of these countries. Without opposing this view one can see how the desire to bring these important facts to the attention of the public may have led them, inadvertently, to take occasionally a rather odd position.

For example, in an introductory paragraph we read that: "A degree of fluctuation such as that indicated by this study threatens underdeveloped countries with inflation in both prosperity and depression. During recessions, reduction in export proceeds and balance of payments deficits encourage the devaluation of currencies or restriction of imports; both measures may increase inflationary pressure on prices. Conversely, the money income of exporters may expand so rapidly in times of increased demand that domestic controls become inadequate to prevent inflation. . . ."

Surely this is making the worst of both worlds! If during a recession an import surplus ensues, the result may be an internal deflation. This would be symmetrical with a resulting inflation when the country has an export surplus. On the other hand, if, for argument's sake, we allow the country with an import surplus to devalue its currency (or restrict imports), thereby courting inflation, we must, by the same logic, allow that if it revalues its currency (or removes import restrictions) when the value of exports expands, it exerts a deflationary pressure. There may, of course, be factors which render a symmetrical analysis of this sort inapplicable for many of the underdeveloped countries. If so, it would be more convincing to indicate their nature at this juncture rather than to lean so heavily on the indulgence of the sympathetic reader.

On page 20, after telling us that there were continuous long-term trends ". . . resulting in total changes in commodity prices which were greater than the normal total cyclical amplitude," we meet with the remark "clearly in respect of long-term projects or long-term planning, a steady and persistent adverse long-term trend can be just as destructive of stability as shorter-term fluctuations." Now this opinion, as it stands, is not easily acceptable. The concern with stability *per se* can be taken too far. After all, there is a presumption that the price mechanism has a rôle to fulfil in the economy: and though a good case can be made for reducing short-term fluctuations, it is usually made with a proviso that long-term trends should be allowed to prevail.

The attempt in Chapter 5 to impute the respective contributions of price variation and volume variation to variations in export proceeds may be a

neat way of summarizing the main results of previous chapters, but we must be aware of slipping into unwarranted inferences. To illustrate, on page 62 there is the following paragraph: "Price stabilization alone, without stabilization in volume, would, therefore, have reduced the cyclical instability of proceeds by only ¼. Similarly, stabilization in volume, without price stabilization, would have reduced the cyclical instability of proceeds by only ⅓. In both cases, other things being equal, the major part of existing cyclical instability would have remained in spite of such partial stabilization."

From the observation that partial stabilization is inadequate, we may unthinkingly draw the conclusion that stabilization of both price and volume is required. But in some cases, where changes in supply are largely responsible for fluctuation in export proceeds, stabilization may be effectively increased, not by adding volume stabilization to price stabilization, but by removing price stabilization entirely. This is at once recognizable in the limiting case of an import elasticity of demand equal to unity.

But, after all criticisms have been made—and many of them are really in the nature of a request that the scope of the report be enlarged—anything said, or left unsaid, should not be allowed to detract from what, by any standards, is a solid achievement in applied statistics.

E. J. MISHAN

Federal Reserve Bank of New York

Ausgleichsgesetze der Amerikanischen Zahlungsbilanz. By JÜRG NIEHANS. (Berne: A. Francke. 1951. Pp. x, 173. Sw. fr. 9.50.)

The author attempts to make general price theory the basis of quantitative forecasting in the field of international economics. In particular, he wants to find some "economic laws" to explain the movements leading to an equilibrium in the U.S. balance of payments. In the first, theoretical, part of his book he defines "equilibrium" and "disequilibrium" in the balance of payments as absence or presence of divergencies between intended and actual international transactions. He divides equilibrating movements into "visible" and "invisible" ones (depending upon the possibility of actual verification in balance of payments statistics), subdividing the "visible" movements into "monetary" and "administrative" ones (depending upon their effects on "freedom" of private international market transactions). Finally, he distinguishes primary, secondary, and tertiary consequences of equilibrating movements. The first category includes effects on prices and quantities of goods and services entering international transactions and depends mainly on the price elasticity of demand for these goods and services. The second includes effects of primary changes on incomes as well as on prices and quantities of other goods and services. The third includes effects of primary and secondary changes on the future decisions of producers and consumers.

In the second, quantitative, part of the book, the author tries to estimate price elasticities for U. S. imports and for U. S. foreign travel expenditures, primarily on the basis of data covering the period from the middle of 1947 to the beginning of 1949. He analyzes 18 commodity groups, which accounted in

1948 for 46 per cent of all U. S. imports, comparing in most cases the volume of imports with the relation between domestic and import prices. He comes to the conclusion that about half of the goods have a short-run elasticity of less than unity, and about one-fourth an elasticity of more than unity while the elasticity of the rest is either unity or indeterminate; however, almost two-thirds of the goods have a long-run elasticity equal to or greater than unity. The author also calculates that foreign travel has an elasticity of more than unity.

Analyzing the relations between imports and exports as well as between imports and national income, and observing the modest rôle of foreign exchange in the U. S. banking system, the author finds that changes in U. S. imports have negligible secondary and very small tertiary consequences. The net effects of changes in U. S. imports are therefore virtually identical with their primary consequences and thus determined by the price elasticity of demand for the affected goods and services. For this reason, the trading partners of the United States can hope to raise their total dollar earnings only by means of selective rather than indiscriminate reductions in the prices of their export goods (or even in U. S. tariff duties). The author advises the European countries to concentrate on technological progress so as to be able to export "newly invented" goods to the United States.

The author performs a useful service by applying good old-fashioned price analysis to the most pressing problem of modern international economic theory and policy, and his conclusions conform to common sense. However, the statistical basis of the study is far too narrow to furnish conclusive evidence for his estimates of price elasticities and thus for the validity of his practical conclusions. Nevertheless, in a world which abounds in facile generalizations on the future of the U. S. balance of payments, it is refreshing to encounter a conscientious attempt to bring the discussion back into the confines of scientific method and quantitative measurement.

J. H. FURTH

Washington, D.C.

International Economics. By CHARLES P. KINDLEBERGER. (Homewood, Illinois: Richard D. Irwin. 1953. Pp. xx, 543. $6.00.)

This comprehensive work integrates the newer developments in the theory of international trade and finance with standard classical doctrine in so far as the state of our knowledge permits. It employs the analytical approach and consistently applies theoretical tools to the problems of the real world. Descriptive material on bills of exchange, gold standard, etc., has been held to a minimum and the treatment of institutions is shorter than in most textbooks. The style is clear and sprightly, considering the difficult and complex nature of the subject matter.

The organization is excellent. In Part I, the necessary groundwork dealing with balance of payments, foreign exchange markets and elements of the adjustment process are held to 75 pages. Part II covers the heart of foreign trade theory and its application to commercial policy. Part III deals with

capital movements and the process of economic development. Part IV, which is about one-fifth of the book, treats the forces of disequilibrium and the means of adjustment.

The two key chapters, on (1) the price mechanism and classical assumptions and (2) income changes and the multiplier, include 22 diagrams and several tabular illustrations which will facilitate the teaching of these subjects.

In addition to the customary subjects, the tariff chapter deals with the terms of trade, factor returns and redistribution of income. "Trade substitutes for factor movements. Imports reduce the scarcity of the scarce factor; exports lessen the redundancy of the plentiful factor. . . . More than simple redistribution between industries is involved. . . . Labor intensive types of manufacturing—shoes, textiles, pottery, hat bodies, etc.—are the strongest proponents of tariff protection. Large scale manufacturing in mass-production industries, on the other hand, employs a predominance of the abundant factor, capital, and is identified with exports. As capital became more plentiful than land and as the role of agriculture products in exports shrank, large scale manufacturing industry swung from protectionism to export-mindedness, and agriculture from free trade to protection. This explains much of the reversal in United States trade policy" (pp. 200-01).

A chapter on monopolistic discrimination and two chapters on quotas, state trading and exchange controls emphasize the importance of these devices in the world today. Exchange controls against scarce currencies are treated rather fully and Frisch's trade matrix is explained. Under certain conditions, discrimination may reduce total trade less than would proportional reductions in trade. The final chapter of Part II on "The Case for Free Multilateral Trade" brings out the difficulty of putting Humpty-Dumpty together again. "The condition that every country have a balance in its international accounts or reserves large enough to cover its gross deficits in inconvertible currencies has given us an example of the fallacy of composition. Each country has to run the risk of losing a lot—its reserves—in order to achieve a problematical gain-convertibility—which accrues as much or more to others" (p. 280). The discussion is enriched by an all too brief evaluation of the risks of multilateralism in a dynamic world of imperfect markets.

Almost 100 pages are devoted to capital movements, the transfer process, and economic development. The classical explanation of the transfer process is criticized and the modern theory expounded. An effort is made to cope with the intricacies of the terms of trade with the conclusion that something can be said, but not much that is conclusive. The stages of economic development in relation to factor proportions and balance of payments receive the attention that seems to be warranted by interest in the problems of growth.

The last 130 pages (Part IV) are devoted to disequilibria and the means of adjustment. Here Kindleberger breaks new ground in the treatment of structural disequilibrium at the factor level and the spending of inconvertible foreign currencies on higher priced goods. This is only incidental, however, to a full review of the appropriate measures to correct disturbances.

Cyclical disequilibrium may arise from differences (1) in the international timing of business fluctuations, (2) in income elasticities, and (3) in price elasticities. Depreciation, deflation and import controls are each regarded as unsuitable remedies. This leaves short-term lending. But cyclical disequilibria do not balance out over the full cycle. For this reason, secular disturbances must be eliminated before the International Monetary Fund can function effectively (p. 433). With respect to secular unbalance, Kindleberger believes that the International Bank and Point Four may have increased the disequilibrium by encouraging boldness in the ambitions and investment plans of young countries.

In the early stage of national growth, planned domestic investment tends to exceed savings, and imports to exceed exports. Secular disequilibrium will arise because the import surplus tends to exceed the foreign capital available for financing it. With the young creditor nation, planned savings tend to exceed domestic investment and exports to outrun imports. To restore balance, Kindleberger tries out exchange rate adjustment, tariffs and other controls. He concludes that "the major remedies are deflation and borrowing in the young countries; maintenance of income and lending in the developed (p. 451).

Structural disequilibrium is the result of wars, crop failures, changes in techniques, taste, etc. The acute difficulty arises when the standard of living must be reduced. The classical medicine is to avoid inflation and depreciate the exchange rate. But when the dislocations are large and resources are rather immobile, a certain amount of inflation may facilitate the process of shifting resources during the period of adjustment to lower levels of living and investment. Kindleberger believes that the planners' prescription may work in the early and acute stages, but as the relocation of resources gets under way, the liberal prescription is called for. The use of quotas will do much more harm in the case of structural disequilibria than in the case of short-term cyclical disturbances.

Kindleberger has carried the analysis of structural disturbances to the factor level. Labor is likely to be overpriced and capital underpriced. "Balance in the balance of payments may still be possible, but only at the cost of unemployed labor . . . the income generated by the employment of the excess labor would spill over into imports and upset the previous adjustment" (p. 461). The deflationary policy of the Italian government under the European Recovery Program has gone far towards balancing the international accounts, but has left structural unemployment.

Clearly, it is desirable to equalize factor returns within the country, but this is hard to achieve. Political and social as well as economic adjustments are required. The difficulty with the prescription of lower wages and higher interest rates "is likely to be that it will not work" (p. 465). Workers may prefer unemployment and it is by no means clear that business will substitute labor for capital at lower wages and higher interest rates.

In a concise review of the European Recovery Plan, the author correctly points out that circular reasoning is involved in using balance of payments analysis to determine the level of American aid. He finds that the argument

that suppressed inflation must end in open inflation is not supported by the European experience.

The concluding chapter sums up what can be done with the four disequilibria—cyclical, secular, structural goods level and structural factor level. The four means of adjustment are trade restrictions, capital movements, price and income changes. "Trade restrictions are to be avoided, capital movements can be regarded as a way of buying time" (p. 502). This leaves the field chiefly to fiscal policy and depreciation of the exchanges.

At a highly abstract level it would seem that structural disturbances could be handled by price changes and cyclical and secular disturbances by fiscal and monetary policy. Some of the problems are that: (1) One country alone will have difficulty during cyclical and secular disequilibria with fiscal and monetary measures; (2) The cyclical remedy may not work unless the secular disequilibrium has been corrected; (3) The price system may correct structural disequilibrium at the goods level or it may shift resources chiefly to industries producing for domestic consumption. In the last case, depreciation will be needed.

What is most undesirable is inflation balanced by quota restrictions. The conclusion is that there is no one sovereign remedy. The world should work toward the restoration of mobility of resources, revive lending, and maintain fairly stable exchanges. "Cases will still occur in which trade controls are unavoidable."

The author has performed a service in bringing together the old and the new in the field of international economics. The relevance of theory to policy is demonstrated throughout the last half of the book. By infusing the analytical treatment with a fair degree of realism, more questions are raised than can be answered. The important thing is that the tools of analysis are brought to bear on the problems in an orderly way.

The annotated bibliography is extremely useful. Surely this is the way bibliography should be handled in textbooks. The comments are brief but enlightening and stimulate further reading. Graduate students and others who have been unable to keep up in the field will appreciate this feature.

The book, I believe, will be widely welcomed as a text. The only question is whether it is too difficult for undergraduates. The liberal use of diagrams is helpful on this score. The work probably covers too much ground for a one-semester course, but there should be no difficulty in omitting certain chapters.

Duke University

D. D. Humphrey

International Economic Organizations. By C. H. Alexandrowicz. Published under the auspices of the London Institute of World Affairs. (New York: Frederick A. Praeger. 1953. Pp. xii, 263. $6.00.)

Although some of the present international economic organizations originated in the last century, *e.g.*, the International Telecommunication Union and the Universal Postal Union, their proliferation became most evident during the past decade. Professor Alexandrowicz' study attempts a summary of

their internal administrative structures, as well as their main economic objectives and achievements. That this is no easy task to compress into less than 300 pages can be seen from his list of abbreviations, covering some forty agencies, both worldwide and regional. Paticular attention is given to the gold standard and international cartels, representative of privately initiated international organization; quasi-public groups such as the International Co-operative Alliance, the International Chamber of Commerce, and the Bank for International Settlements; and the Bretton Woods agencies, the International Trade Organization (never ratified), the International Labour Organization, and the U.N. Economic and Social Council, international organizations at the government level.

Because of space limitations, the descriptions are hardly more than summaries, with many necessary qualifying remarks omitted. Hence the reader should be fairly well informed about the general economic background during the past 75 years in order to comprehend and assess the author's judgments, such as those about the gold standard mechanism. Otherwise he may get a somewhat distorted picture; the International Monetary Fund, for example, is made to appear in too unfavorable a light.

The order in which the agencies are treated emphasizes two themes: the gradual development of the tendency to organize internationally to cope with the emerging economic problems, and the increasing tendency for governments to play a more important rôle as the functions shifted from the technical to the policy-making, private and short-term planning developing into public and longer-term planning. For example, the informal central bank cooperation within the gold standard has given way to the formal representation of Treasury officials on the International Monetary Fund. This frequent use of the pre-1914 gold standard as a yardstick makes one feel that the author's ideal would be a supergovernmental agency run by international civil service experts according to set rules, with the "power politics" departments, such as the Foreign Offices, excluded, since these are too nationally minded.

A characteristic of the period since World War II has been the increased decentralization of functions among many agencies, in contrast to the greater centralization within one, such as the interwar League of Nations, or Lord Keynes' proposed International Clearing Union. Part of this the author attributes to the excessive zeal for new agencies resulting from "an inherent trend towards an expanding international bureaucracy."

Cooperation among nations depends on whether or not isolation can be afforded, or alternatively, whether the administering agency can force compliance through the threat of withdrawal of its services. The coal shortage enabled the European Coal Organization to succeed; the lack of similar effective sanctions has weakened other agencies, *e.g.*, the inadequacy of the International Monetary Fund's resources relative to the size of the dollar shortage. (Under the gold standard the desire to maintain a fairly rigid gold value for the country's currency served as the necessary sanction to keep members "in line.") Hence it would be better not to have any organization than a meaningless and ineffective one, for the lack of any organization would highlight the

fact that the problem involved was still unsettled, so that it might be tackled again at a later, more appropriate time.

The author points out that in aiding underdeveloped areas, some government intervention is needed where private initiative will not step in; but too much may be just as great a hindrance to developmental cooperation as too little. In fact, world community building is hindered whenever there is government intervention, even internally, for its policies as a member of an international organization will be designed to protect its own domestic planning, rather than being aimed at the broader issues.

Unfortunately, the book has many shortcomings, which a carefully edited reissue could overcome. Most serious is the complete omission of the repercussions of the Korean invasion (although unconnected post-Korean developments like the European Payments Union are discussed). For example, the author does not treat the U. S. government's price controversies with the tin and rubber producers in his sections on those commodities. No mention is made of the International Materials Conference.

The organization of the book could be improved considerably, too. Although the emphasis is on the organizational structure of each agency, there are many short asides—often at irrelevant places—on general principles inferred from these individual studies. Greater space than a sentence or two should have been allotted the interwar League-sponsored loans guaranteed by other than the debtor government, and the international trade union movement. Errors in style, such as the use of four different titles for the Export-Import Bank in Chapter 13 (*e.g.*, United States State Bank) should also be corrected, as well as mistakes in several of the descriptions.

Despite these minor defects, the book should serve as a compact introduction to the subject, and as a guide to the reader interested in learning more about the agencies discussed. As the author remarks, "the interest of the international lawyer and of the international economist coincide, as the structure of the organization is particularly essential for the performance of its functions."

Business Administration

City Milk Distribution. By R. G. BRESSLER, JR. (Cambridge: Harvard University Press. 1952. Pp. xii, 398. $6.00.)

In this exceptionally interesting analysis Bressler evaluates several proposals for improving the efficiency of milk distribution. Since he considers only the movement of fluid milk in bottles or containers from processing plant to consumer, his field of study is fairly narrow. The flow of milk from farm to plant, distribution to consumers through restaurants and other "institutions," and the marketing of other dairy products, all lie outside his subject. Geographically, his field studies have been restricted to Connecticut, so that here

too the area of analysis is narrow. What he has lost in breadth, however, is more than made up by the depth to which he probes.

The general nature of the study is set when he defines efficiency as a ratio between input and output. Given this definition, his problem becomes one of finding out how the proposals to be evaluated would change the present input-output ratios in a number of sample markets. The unit of output taken is simply a quart of milk delivered to the consumer. For some purposes quarts delivered to the consumer's home are treated as equivalent to quarts handed across the counter of a retail store; for other purposes they are defined as different units of output. The unit of input measured is an aggregate of cents' worth of route-labor cost, route-truck cost, and processing-plant cost per quart of milk delivered.

Nearly all the data were collected during 1940, 1941 and 1942 in the course of a study of milk distribution made under Bressler's direction at the Agricultural Experiment Station in Storrs, Connecticut. Much of the material has already been published in a series of short reports issued under the general title *Efficiency of Milk Marketing*. Considerable sections of the book under review are quoted almost verbatim from these reports. It is much more than a scissors-and-paste assembly, however, and should be approached as an essentially new and significant book.

Bressler's primary concern is a belief that the present mixture of competition and monopoly has resulted in a wasteful duplication of delivery routes and plants, as well as in a waste of manpower for unnecessary or even undesirable competitive selling. He undertakes to measure the waste by seeing how much costs would be cut by each of the following methods of reducing excess capacity: substitution of alternate-day for daily deliveries; rearranging routes so as to give each present plant an exclusive territory or a territory shared with only one or two other plants; converting the delivery of milk within a given city into a monopoly with a single plant and no duplication of routes, the concern to be operated either under regulations appropriate to a public utility or as a municipally owned and operated enterprise; and elimination of house-to-house delivery so that all consumers must buy their milk in retail stores.

In measuring the probable effects of such changes, Bressler first makes a detailed cost allocation. He then works out a long series of equations relating cost of delivery per quart to such variables as quantity of milk delivered per mile of roads and streets in a given market; quantity delivered per mile of delivery routes, including duplications; the size of a processing plant; and the proportion of processing-plant capacity used. In a third step the effects of the proposed changes upon deliveries per mile and upon plant utilization are computed. Finally, the equations translate these effects into costs per quart delivered.

Bressler concludes that the introduction of alternate-day deliveries has already reduced costs by 1.8 to 2.6 cents per quart in the markets studied, as compared with what they would be under a system of daily deliveries. Each of the other proposals for reorganization would reduce costs still further, the

maximum advantage being obtainable under a municipally owned monopoly. Such a monopoly would reduce costs by an additional amount ranging from 2.3 to 4 cents a quart in the various markets. Substitution of store sales for house-to-house deliveries, if reinforced by a reorganization of wholesale delivery routes, would cut costs still further by an amount on the order of 2.4 cents a quart. From a somewhat limited field survey, it is concluded that most consumers would approve of the various changes in return for the estimated savings, except as regards elimination of house-to-house deliveries.

The space here available precludes a detailed evaluation of the methods Bressler uses and of the conclusions to which he comes. Two precautionary notes must suffice: First, although the methods used in allocating costs are well defended, they rest upon a host of debatable assumptions, estimates, and judgments. Secondly, the conclusions reached cannot serve as a basis for action in a specific market without bringing back into account many factors eliminated by the definition of the problem or touched very lightly in the analysis.

Despite these limitations the book makes an important contribution to the literature of marketing. It deserves wide reading, especially among those concerned with the statement so often made that marketing is inefficient and wasteful. Not only in its conclusions, but in its approach and methods, it marks a significant advance toward reducing that naggingly persistent question, "Does distribution cost too much?" to forms capable of meaningful measurement.

REAVIS COX

University of Pennsylvania

Studies in Costing. Edited by DAVID SOLOMONS. (London: Sweet and Maxwell. 1952. Pp. xii, 643. $5.95.)

This book, a companion volume to *Studies in Accounting* by W. T. Baxter, is published on behalf of the Association of University Teachers of Accounting. With the main purpose of providing supplementary readings for accounting students, the editor, a member of the faculty of the London School of Economics, has collected what seemed to him to be the best contributions on cost accounting in the English language during the last twenty years. This reviewer believes that a number of these essays will be of value to students of economics, and that the book should also appeal to professional accountants and industrial engineers. The twenty-six articles selected are almost evenly divided between British and American authors and consist mainly of critical discussions of principles. A rough classification of the essays by authors shows that eight were written by economists; five by teachers of accounting; three each by public accountants, industrialists, and the committee on research of the National Association of Cost Accountants; the remaining four by engineers and teachers of law and history.

The first section contains two articles on the history of cost accounting. The essay by Solomons shows how the need for cost records came with the factory system and the great increase in the size and complexity of modern business. The distinction between fixed and variable costs was recognized by both

economists and accountants at an early date. In the beginning, records were kept for material and labor costs and crude estimates for overhead were added. Hamilton Church made important contributions with his ideas of production centers, burden distribution, and a supplementary rate to take care of idle time. In this country, a great impetus to cost accounting came through the work of Frederick C. Taylor. During this early period when cost systems were developing, a number of controversies took place not only as to such questions as overhead distribution but also as to what cost should include. When the importance of normal rather than actual rates of production was recognized, the next logical step was the concept of a predetermined or planned cost. Although each decade has brought refinements in techniques, emphasis on different aspects such as budgeting or distribution costs, or more recently the attempt to study the relation of cost to output, Solomons believes there is little in modern cost accounting that our fathers did not know.

The second division consisting of five essays deals with the concepts of cost. As might be expected, these articles by Theodore Lang, R. C. Edwards, and others bring out that cost concepts are much more diverse and complex than is generally assumed. In spite of the early and long controversy on such matters as whether interest should be included in cost, there are still substantial differences of opinion as to what constitutes cost. Also, costs cannot be classified into two distinct classes of fixed and variable. Even direct material cost at a particular time will differ according to the method of inventory used. As final costs are not known until the end of the accounting period, burden must be applied by the use of predetermined rates. Where there are multiple products, which is usually the case, some decision must be made about splitting up joint costs on a logical basis, or in other cases some value of a by-product must be determined as a credit to the main stream of costs. In many instances, cost is the best estimate management can make for a certain purpose.

The third section, which consists of nine articles and deals with cost as an instrument of planning and pricing, will be of particular interest to students of economics. Here will be found the excellent article on short-period price determination by R. A. Gordon, reprinted from the *American Economic Review* of June 1948, in which he reviews the Lester-Machlup controversy over marginal analysis. When we consider multiple products, selling costs, noncompetitive markets, and imperfect knowledge of demand, the marginal cost-revenue approach of the average economics text is very superficial. Because of ignorance and uncertainty, the entire analysis becomes unrealistic. Unable to deal with so many variables and with a desire for a strong and secure financial position, the businessman may rely on average total costs rather than seek maximum profits by use of marginal costs. In Gordon's opinion an explanation of business decisions resting on subjective factors is not satisfactory. The material contained in the article by Joel Dean on the break-even analysis will be familiar to American readers of economic literature. Dean contrasts this device with the flexible budget; outlines various approaches to the data by statistical, accounting, and engineering methods; and shows the difficulty

in arriving at a satisfactory means of measuring the rate of output. Dean is also careful to make the reader aware of the limitations of this management tool. In one of these essays, W. T. Baxter develops arguments for concentrating on prime cost, with an allowance for opportunity cost, instead of trying to arrive at full cost in the traditional manner. In this section, there is also an article on distribution costs, a subject which many believe has been neglected until recent years. Sections four and five are concerned with cost as a means of control and cost in the service of government.

Although the economist may not find much new material in these essays and the professional accountant or businessman may not, as a rule, be interested in topics such as the recent marginal-analysis controversy, this volume does help to bring together useful material about one area of actual business practice and the economic writings on the theory of the firm. No book can cover all aspects of managerial economics. As this book is concerned with cost, it gives only a limited approach to the much broader problem of showing how economic analysis can be used to formulate business policy. These essays contain little about demand theory or the various competitive situations under which price is determined. The theorist has yet to explore selling costs in a satisfactory manner. As many of these essays were written a number of years ago, new material on topics such as statistical determination of marginal costs is not included. The student will also have to look elsewhere for an adequate discussion of the proposals now being made for accountants to measure costs and income in units of equal purchasing power instead of the ordinary dollar unit.

This book will have a definite value to students of business, for it will give them a much broader concept of cost than is gained from the usual texts. Any attempt to determine cost is beset with many difficulties. Actually, cost has no precise or objective meaning. W. H. Hamilton, in one of the concluding essays of this volume, "Cost as a Standard of Price," speaks of accountancy as a "scheme of notation, a language, a technique, . . . and a social institution" (p. 598). Expressing it more simply, we may well conclude that cost is whatever one says it is.

LAWRENCE R. CHENAULT

Industrial Organization; Public Regulation of Business

Entflechtung und Neuordnung der westdeutschen Montanindustrie unter besonderer Berücksichtigung der Verbundwirtschaft zwischen Kohle und Eisen. By HELMUT HENNIG. (Bern: A. Francke, 1952. Pp. viii, 240 Sw. fr. 22.—.)

This well documented and carefully reasoned book deals with the effects on the German economy of the liquidation of her coal and steel combines. After a brief outline of the immediate postwar situation of these key industries and the impact of the numerous, often contradictory, laws and regula-

tions issued by the allied powers, the author demonstrates the need for horizontal and vertical integration in these industries. In his opinion, the main economic reason for horizontal integration is the greater ability of large, multiple-plant firms to withstand fluctuations in demand. In periods of recession large firms can shut down their marginal factories and concentrate production in the more efficient plants. Furthermore the expense of switching from one product to another with changes in demand is minimized, because each of the many plants controlled by one firm can specialize in one type of product. The economic advantages of vertical integration are seen in a regular supply of qualitatively uniform raw materials and reduction of transportation costs. The ability of integrated firms to allocate joint costs in a way which will reduce the price of some high cost products is believed to be particularly important. Internal subsidies make government grants unnecessary and avoid the latter's unfavorable effects on allocation of resources.

The present structure of the German coal and steel industry is illustrated with the help of 43 charts. The far-reaching economic effects of deconcentration on the efficiency of these industries are clearly demonstrated. Their competitive position in the framework of the European Coal and Steel Community is expected to be particularly unfavorable in view of the increasing integration tendencies of the other member states. Special emphasis is given to the postwar nationalization of the French, Dutch and Italian coal mines and the large-scale public (Italy) and private (France) concentration of the steel industry in other countries.

This reviewer has no quarrel with the economic arguments presented in favor of re-integration of the German coal and steel industry; this in spite of certain restrictive practices exercised by the prewar German combinations and the dominant influence of the latter on the policies of the International Steel Cartel. The prevailing consensus of European writers on the subject is that free competition in these lines of industry is unworkable. In the absence of an agreement, high fixed costs cause price wars in periods of declining demand resulting in great losses to the companies concerned. However, in the case of Germany economic considerations have to yield to political realities. France can hardly be blamed for her insistence that these *Konzerns*, keystones of the German war potential, be dissolved, even at the cost of economic inefficiency. These political factors were ignored by the author.

HERBERT C. WITTGENSTEIN

Stanford University

The Economic Blockade. Vol. I. By W. N. MEDLICOTT. (London: H. M. Stat. Office and Longmans, Green. 1952. Pp. xiv, 732. $8.00.)

This is the first of two volumes describing the blockade activities of the British government in World War II. These activities were largely conceived and directed by the Ministry of Economic Warfare, and the two volumes will constitute the official history of MEW. Like the U. S. Board of Economic Warfare, MEW was a wartime agency dissolved shortly after the cessation of hostilities. The volume under review, which carries the story generally to mid-

1941, was drawn almost entirely from official documents, to which the author had complete access. The conclusions, however, are the responsibility of the author.

The success of the British blockade against Germany in World War I led to substantial reliance upon this instrument in the plans and hopes of the British government at the outbreak of war in 1939. As events turned out, the different character of this war resulted in the relegation of the blockade to a subsidiary rôle in the final defeat of the Axis. Nevertheless, the activities in question were pursued vigorously, especially during the first two years of the war, and their ultimate contribution to the allied victory will probably never be completely evaluated.

The purpose of the blockade was to prevent the importation into Germany, directly or indirectly, of supplies which would aid that country in the prosecution of the war. The initial and traditional system for its accomplishment was the interception and detention, by the British Navy, of vessels suspected of carrying contraband items ultimately destined for Germany. An official list of contraband was published and widely disseminated. Intercepted vessels were turned over to control bases where a careful investigation of cargoes could be made. A Contraband Committee, after investigation, decided which items should be formally seized and which allowed to proceed to their destination. In flagrant cases of contraband traffic, the carrying vessels were also seized and disposed of by decisions of the Prize Court.

The success of the blockade depended upon a number of major factors. A constant stream of information from all parts of the world was needed to determine in advance the movement of cargoes and vessels, the affiliations of consignors and consignees, the precise nature of the supplies involved and the possible uses to which they could be put. Intensive studies of the German economy were made to determine its material needs and resources, its reserve supplies, and its economic vulnerability. The various informational activities of the Ministry were directed by its Intelligence Department, but heavy reliance was placed upon British consulates and other representatives throughout the world.

A second major factor was the conduct of the blockade in such a way as to minimize the antagonism of neutrals. This was a most delicate task, especially in the case of the United States. Apart from questions of face-saving and national sovereignty, the United States government—particularly between the outbreak of war in Europe and mid-1941—had to contend with powerful internal isolationist sentiment, problems of the election year of 1940, and the occasional representations of commercial and shipping interests. A particularly thorny problem was the agitation for relief measures, including the shipment of food, to occupied and nonoccupied portions of Europe after the fall of France. The British position that such shipments would inevitably help the Axis was seriously challenged by certain groups and individuals in America, most notably represented by Herbert Hoover. In many instances, the official policy of MEW was overruled by the British Foreign Office and even by Mr. Churchill himself, when friction with the United States was concerned. This

often led to discriminatory treatment of other neutrals, with politically awkward consequences.

A third major problem was that of administration in all its ramifications. The patrol responsibilities of the thinly spread British Navy had to be minimized and concentrated in the most effective areas. This led to efforts to apply various controls at the sources of supply and to obtain restrictive agreements from neutral governments as well as from major firms and associations of exporters, importers, and shipping companies. The complex story of these negotiations is systematically presented on a country by country basis. Equally well portrayed is the development of the system of contraband controls, the use of "commercial passports" or "navicerts," and the rationing of supplies to neutral countries adjacent to Germany.

Like many wartime agencies in the United States, the Ministry suffered from rapid growing pains, insufficient personnel (especially typists), lower pay scales than competing agencies, and the frustrations of "Treasury red tape." Of interest to economists is the following observation upon the qualifications desired of MEW personnel: "It was decided from the start that although the word 'economic' was used to describe the functions of the Intelligence Department, it was not desirable to use too many individuals whose specialized training lay in the field of academic economics. For much of the work a good technical training and the capacity to weigh evidence in one or other field of applied science, or experience in applied research in such fields as engineering, transportation, and agriculture, was considered to be much more valuable than a formal training in economics. A small number of individuals with high academic qualifications in economics and statistics was, however, included in specialized fields such as finance and manpower" (pp. 66-67).

The author has done an admirable job of organizing and presenting a most complicated story. His exposition is interesting, direct, and crystal clear. The book includes statistical and documentary appendices. The complete absence of footnote documentation contributes substantially to the book's readability, without sacrificing the reader's conviction of solid reliability and sound scholarship. No doubt it was this sensible omission which made possible the completion, in something less than nine years, of a task which might easily have run to half a lifetime.

R. Elberton Smith

Office of Military History,
U. S. Army, Washington, D.C.

Review of Small Business. Final Report of the Select Committee on Small Business, House of Representatives, 82nd Cong., 2nd Sess. (Washington: Supt. Docs. 1952. Pp. xv, 310.)

This report, completed during the last moments of the 82nd Congress, deals with a wide range of significant small business problems. A short introductory chapter discusses the concept of small business and sketches a framework for the remainder of the report, while wisely leaving a precise definition of "small business" to others. Eight chapters follow, each dealing with a

specific problem or related group of problems: economic controls, financing, federal taxes, government procurement, government counseling, Small Defense Plants Administration, antitrust program, and unfair competitive practices.

Indecisiveness in the post-Korean stabilization program, leading to unnecessary harassment of small businesses, is deplored, and an orderly decontrol program, leaving limited emergency price freeze authority to the President, is recommended. Although the Office of Price Stabilization is given credit for stopping scare buying, and its Office for Small Business (thought by some ex-OPS personnel to be the most useless appendage of that agency) is praised, OPS operations as a whole are severely criticized. Complaint is made of "technical procedures," "legalistic terminology," and delays in granting individual price adjustments. Also, onerous filing and record-keeping requirements are castigated. The Committee gives no indication of any awareness that standardized (*i.e.*, technical) price control procedures are alternatives to control by individual whim, that legalistic terminology may be desirable for legal documents in a world where court cases are argued by lawyers and decided by judges, and that Congressional slashing of OPS funds at a time when adjustment pressure was at a very high level may have contributed to the ensuing delays. Nor does it recognize that filing and record-keeping requirements, in addition to making available indispensable price control information, have a salutary effect on compliance and greatly simplify enforcement problems. The Committee may be on more solid ground in attacking the OPS Industry Advisory Committee program (in effect, a temporary Sherman Act suspension), procrastination in issuing tailored regulations, and the failure to roll back prices which were raised hastily during the period of so-called voluntary stabilization in anticipation of a price freeze.

To alleviate the difficulties encountered in obtaining long-term loans as a substitute for equity capital, the Committee feels that the Reconstruction Finance Corporation should be continued at least until other adequate financing methods, such as government insurance of long-term bank loans, for example, are developed. While the continuing need for large amounts of government revenue is recognized, it is pointed out that high surtaxes and excess profits taxes impose a particularly severe handicap on small firms, and that consideration should be given to revising the tax structure in several ways calculated to ease this burden. After a fairly detailed discussion of the activities of major governmental procurement agencies, the Committee concludes that although the basic procurement laws themselves are not adequate for small business protection, the administration of such law as exists has been even more inadequate.

A brief outline of federal and state counseling and informational programs is presented, together with conclusions that such programs have been more successful during emergency periods than during peacetime, and that an independent federal counseling agency is more desirable than ununified small business programs conducted by several different agencies. The activities of the Small Defense Plants Administration are described in a laudatory manner,

and a recommendation for the continuance of this agency is included. The Committee finds, and fears, a continuing trend toward economic concentration, which has been stimulated by the post-Korean semimobilization, and which has not been countered effectively by haphazard antitrust enforcement. Federal Trade Commission action, and inaction, during recent years is discussed, and most of the blame for the Commission's ineffectiveness is attributed to conflicts and low morale within the Commission, although statutory deficiency also is recognized.

Despite the fact that some passages of the report remind one of the sound and fury of those who professionally champion small business, whether or not it needs or desires a champion, the abundant factual material presented, including sixty-four tables and charts, should be very helpful in a variety of university courses dealing with the problems of small business. Provocative discussions could be developed around many of the Committee's conclusions and recommendations.

ROY J. SAMPSON

Forest Grove, Oregon

Public Utilities; Transportation; Communications

World Airline Manual, 1952. 4th ed. (Chicago: Roy R. Roadcap. 1952. Pp. 400. $12.50.)

This reference annual appears within a year after the close of the period covered, the 1952 edition providing 1951 data. It presents statistics, as comparable as possible, for the regularly scheduled airlines of the world. That means, in this country, carriers holding certificates of public convenience and necessity from the Civil Aeronautics Board, and in other countries, carriers of equivalent status. About 40 per cent of the space is devoted to United States flag services.

Many of the data are available elsewhere, but they are conveniently brought together in this volume. For each air carrier there is presented a brief historical résumé, written in the tradition of the standard financial manuals, together with a list of officers and the firm's address. There follow certain statistical data, such as the population served, the carrier's fleet and its utilization, the volume of traffic of each type, operating revenue and expense accounts, and a balance sheet. Statistical data on foreign lines sometimes relate only to earlier years. For the smaller lines not all of these data are presented; for the larger American lines, in which there is a public stock interest, certain material of interest to the investor also appears. Most carriers have been mapped, ordinarily a simple sketch for foreign lines, while a "service density map," a diagram in which the thickness of the lines between pairs of cities indicates the number of seats (or sometimes flights, when only one type of aircraft is used) scheduled daily appears for most United States flag services. Such service density maps are also presented for the Russian Aeroflot. The maps and analysis of the Russian air service are among the most interesting aspects of the volume, any perspective on things Russian being elusive.

Sources of data are not indicated, but can often be traced. Until 1949, the Civil Aeronautics Board sporadically published an *Airline Manual,* which contained foreign data similar to those presented, as currently as possible, in the volume here reviewed. The data on United States flag airlines seem largely taken from the civil Aeronautics Board's *Recurrent Reports*. The service density maps are presumably based on analyses of the published timetables of the carriers. The corporate financial data, where presented, must have been abstracted from the companies' annual reports.

The volume would have been improved by more careful editing. For example, the recent sale by United of its subsidiary, Lamsa, to Mexican interests, is appropriately indicated in the textual description of United, but is omitted from the discussion of Lamsa. Another example appears in the operating revenue accounts of United States flag airlines. This *Manual* reproduces the unadjusted figures for mail pay, and, following the practice of the Board's *Recurrent Reports,* uses that figure in the summation of operating revenues, and hence, as the component of net income. Retroactive mail pay adjustments are so common in air transport, however, that the *Recurrent Reports* present also a separate figure for adjusted mail pay. For many purposes, a more representative result would follow if the latter figure were used in calculating operating revenues and net incomes. Adjusted mail payments are omitted from the *World Airline Manual.*

This reviewer would be unable to suggest a better published source of material on foreign airlines, although unpublished material may well be available in the files of the Civil Aeronautics Board. For the domestic airlines, however, whether the reader's intent is to find data for scholarly analysis or for financial experimentation, the appraisal must be more reserved. The manual is useful for the first approximation; but the user will probably also quite frequently need to consult the original sources.

JOHN P. CARTER

University of California

Land Economics; Agricultural Economics; Economic Geography

Introduction to Economics for Agriculture. By JOHN DONALD BLACK. (New York: Macmillan. 1953. Pp. xv, 727. $6.00.)

"This book has one clear-cut objective—to give an agricultural college student, or educated farmer or his equivalent, exactly that understanding of economics which he or she needs in order to function effectively and live happily in the world of today." So begins the preface.

The book's economic fabric is woven with strands of the economics of agriculture as the warp and with threads of the general economy as the woof. The cloth is stretched to cover much ground, a necessity if the author is to succeed in providing a single volume "intended to serve the needs both of those agricutural colleges which begin their economics with a course in the economics of agriculture and of those which begin it with a course in the

general principles of economics." The book, thus, is clearly a specialized one for which the author has an admirable, probably unequaled, experience in public service with government agencies and private groups, research, and teaching in agricultural economics at both land-grant and private universities.

If the state of advancement of a discipline were gauged by the improved calibre of college texts, agricultural economics could be judged as making progress. This book by Professor Black contributes much value-added to the stock of teaching materials available for those who prefer a specialized text. Black's text is written in view of what his experience indicates to him to be the needs of students in an agricultural college, especially those students not majoring in economics or agricultural economics and not likely to experience another course in the field. But whether to use a specialized text, rather than one on general principles, is a question to which there need be no universally valid answer.

The text's organization does not follow the current fashion. Rather than considering aggregative aspects, national income and the theory of its determination early in the book, Black introduces some elements of price and value theory immediately after orientation chapters on the organization of agriculture and its setting in a general economy. With that toe-hold, he digs into a series of seven chapters which discuss production economics at an elementary level but in much more detail than is common in the usual introductory text on general principles. Many of these pages cover the same ground as his out-of-print *Introduction to Production Economics* (1926), but it is still good teaching material except for the sections on "efficiency" and "capacity." The relative emphasis on production helps to make this book a differentiated product. So does the emphasis on consumption and commodity distribution.

The six chapters on consumption are short on demand and consumption theory, but long on the type of materials generally found in texts labeled consumption economics. This material, with the chapter on farm family living, can be of interest to those studying home economics. In this part, also, is a chapter on the currently fashionable matrix of food-people-economic development, with consideration of the situations in various countries.

The nine chapters on commodity distribution provide some discussion of price analysis as background, but the emphasis and most of the material is that usually included in a text on marketing. The rest of the book, with exceptions noted below, covers ground common to most texts on general principles. Thus, a convenient way of sharpening the differences in content between this book and the usual one on general principles is to indicate some of the things it omits or only mentions in passing and then indicate what it, but not the other, includes.

Black omits the usual amount of treatment of wages and collective bargaining, labor and industrial relations, theories of national income determination, saving, investment, and alternative economic systems. He includes much material on consumption (not demand theory) and family farm living, commodity distribution with private and cooperative marketing, price margins and

spreads, land use and tenure, agricultural and forestry credit and insurance. Common to both texts are such topics as prices and money, business cycles, equilibrium of the firm, market price determination, use and pricing of productive services, rents, international trade, and public finance. But throughout, Black emphasizes what he calls the "working out" of economic principles, leaving to the instructor most of the task of explaining the logic underlying the principles. An important exception is the economic use and pricing of productive services for which he presents the underlying logic in more detail than is usual in a beginning text.

The exposition is strongly reinforced by some 42 tables and 83 charts, all clearly labeled except one. A wealth of case material is included, and very few topics are discussed in abstract terms without reference to empirical research studies, business practices, or federal and state programs and policies. The treatment is saturated with illustrative materials, although not institutional in spirit or outlook. Instructors seeking a text with adequate case materials and examples will be satisfied. So will those who seek a text in which clarity supersedes sophistication. The writing is lucid and straightforward; the student should have no difficulty in knowing what the author is saying.

The smoothness and ease with which economic problems are discussed and disposed of may cause the mediocre or naive student to be carried away with with the notion that economists know much more than we really do. The brilliant student will wonder often and many times ask "why?" But is it not here that the instructor must play one of his necessary rôles, and how much should one expect from a single text written for the introductory level?

Now, to some evaluation of the text as a tool for teaching economics of (for or in) agriculture. A few slips in elementary analysis have crept in, including the common one of not carefully distinguishing between price elasticity and its relation to the slope at a particular point of the demand curve, as well as a confusion between price elasticity and flexibility and their relation to gross revenue so as to lead to an error concerning relative price elasticities at the farm and retail levels of demand. Those instructors who seek an elementary text which includes a rigorous exposition of economic theory will continue to seek. Those who stress theory in their lectures and desire a text rich in economic problems, the results of empirical research, and the views of a well known expert as to the "working out" of economic principles in agriculture may well find this book a bonanza. But even the brilliant student is unlikely to obtain "exactly that understanding of economics which he or she needs in order to function effectively and live happily in the world of today." A more modest objective, however, can be attained; from this book the student can learn of the types of problems with which economists struggle, if not how we fashion our brittle tools which so often prove inadequate for the tasks to which we put them.

Sidney Hoos

University of California, Berkeley

Agricultural Policy of the United States. By HAROLD G. HALCROW. (New York: Prentice Hall. 1953. Pp. xiv, 458. $5.50.)

Will the policy of high rigid price supports eventually bring on a consumers' revolt, possibly resulting in destruction of the entire price-support program? Are U. S. farm and price-support programs the greatest single cause of the world dollar shortage? These are current issues now being debated within and without this country, and answers to these problems must be sought.

Halcrow's timely textbook on what he calls a "tremendously complicated" subject will go some way towards helping students, political scientists, laymen and—last not least—politicians clarify their ideas on the economic implications of our agricultural policies and programs. This is the first book (others are expected soon) which deals not with isolated policy problems, but with the bulk of them: price, including storage, policies—credit—tenure—conservation, etc. Agricultural labor is one obvious omission.

The book's emphasis is on "economics" and it brings economic analysis to bear on problems of policy by using as criteria three policy objectives, namely, increasing efficiency in agriculture, raising and stabilizing farm income, and improving welfare. These objectives, and the reason for selecting them in preference to others, are discussed in Part II. The analysis of various specified policies and programs in terms of these criteria is pursued in Part III. Part I—The Agricultural Setting—is a description of the agricultural industry and an analysis of the major economic factors effecting changes in the farm population, long- and short-run agricultural production and farm income. This part contains little new material, but is a useful and logical introduction to a discussion on agricultural policy.

Halcrow's approach will satisfy only those who believe that economic analysis is adequate for a complete appraisal and understanding of our agricultural policy. This reviewer is not one of them. There is little history of agricultural policy beyond 1920 to be found in the text, though a well chosen bibliography may lead the researcher into selected subjects. Also, there is hardly any insight to be gained into the question of how actual programs and policies come into being. As a result, his book becomes a somewhat inanimate interpretation of what is actually a dynamic and dramatic phrase of our economy.

Another shortcoming is that in his ambitious effort to master such a broad field, Halcrow has inevitably oversimplified his presentation, and some readers may find it somewhat dogmatic. There are also some seemingly unnecessary repetitions (pp. 144, 165, etc.)

These qualifications do not, however, detract from what is, on the whole, a contribution to the textbook literature in which the author has attempted to treat systematically, rationally and objectively—if at times summarily—a subject with respect to which we are easily carried away by our value judgments. As a textbook for a course in agricultural policy for undergraduate students, this may be precisely what many instructors have been seeking for some time.

ERNEST FEDER

South Dakota State College

Internationale Regulierungen auf dem Weltweizenmarkt. By ANNELIESE BINDER. (Kiel: Institut für Weltwirtschaft, Universität Kiel. 1952. Pp. vi, 93. DM 8.-)

This pamphlet is one of the rapidly appearing sequence of research reports of the Institut für Weltwirtschaft of Kiel. It contains first a brief, chiefly descriptive, monograph on the domestic regulation of the wheat market of the four leading export countries (United States, Canada, Australia, and Argentina) and of the United Kingdom as the leading wheat importer (pp. 6-51). Secondly, it gives in 20 pages a similar matter-of-fact survey of the international wheat agreements. Aside from diagrams in the text and an appendix note with 18 statistical tables with the most pertinent data on wheat there is a tabulated survey on the various dates and provisions of the international wheat agreements of 1933, 1942, 1948, and 1949.

As a brief handbook relating properly arranged reliable information on historial economic facts this survey fulfills its purpose, as do many other pamphlets in this series. The study is not intended to and does not make any effort at coming to grips with the utterly complex economic and political problems involved in international commodity agreements. Hence the few scattered judgments on the merits and demerits of such agreements and on the responsibility of individual nations for certain defects are not to be taken too seriously. Of the wealth of American literature on the subject only the scantiest use has been made, indicating probably the persistent dearth of accessions to the Institut's library covering the war and postwar period.

KARL BRANDT

Stanford University

The Economic Organization of Agriculture. By THEODORE W. SCHULTZ. (New York: McGraw-Hill. 1953. Pp. xx, 374. $5.50.)

The most valuable aspect of this book is not suggested by its title. Part I, "Economic Development and Agriculture," comprising half the volume, belongs in the growing literature which is helping to round out a general theory of economic development. The remaining portions of the study, concerning the short-term instability aspects of agriculture and proposals for organizational policy, have been largely foreshadowed in the author's earlier study of *Agriculture in an Unstable Economy* for the Committee on Economic Development, although here buttressed with more data.

The author describes the book under review as a progress report, drawing heavily on recent investigations at the University of Chicago, as well as on the studies of the Bureau of Agricultural Economics. The book is distinguished by an attempt to provide an empirical foundation for major theoretical propositions which would describe the growth and instability characteristics of the agricultural sector of an evolving economy. These are seen in the peculiar light of a modified consumer's sovereignty theory, under which ordinary notions of causality concerning technology, the food supply, and population growth sometimes appear reversed, as the author acknowledges. Yet he has gone far to reduce such concepts as the income and substitution effects of changes in demand to operational, empirically verifiable terms. The

data are in the main national aggregates for the United States, with principal emphasis on the food crops. However, some illuminating extensions of the general propositions are made to explain features of agricultural behavior in underdeveloped countries.

In Part I Professor Schultz seeks to determine and measure the principal factors affecting the long-term demand for and supply of farm food products. He reviews the population characteristics associated with industrially underdeveloped ("high food drain"), transitional ("intermediate food drain"), and advanced industrial ("low food drain") economies, and concludes that the chief secular influence on the demand for food is its declining income elasticity as population uncoils and the income level increases. An attempt is made to assign magnitudes to the relevant income elasticities.

On the supply side the chief factor is the advance in agricultural techniques, which, operating against the declining secular rate of increase in demand, brings about the chronic surplus (or "farm") problem of advanced economies. This is in contrast to the "food" problem of underdeveloped economies, where increases in output tend to be absorbed by increases in population (unless farm families come to prefer the substitution of property for children). The high productivity of modern agriculture in advanced countries is also shown to account for the declining relative importance of land as a factor limiting economic growth.

The discussion of the development of farm technology is rather unsatisfactory, largely because the author chooses to confine himself to the relatively recent and prospective contributions of publicly supported research agencies. In the lexicon of consumer's sovereignty, this leads to the curious description of the director of an agricultural experiment station as an "entrepreneur," who makes input-output calculations in response to a community preference schedule to "produce" new techniques. The fact that virtually all of this occurs outside a market mechanism makes the discussion little more than a playful analogy, but the implication is left that some day, when the tools of economic analysis have been sufficiently whetted, the processes of scientific judgment and political decision-making involved in such cases will be quantified and empirically tested under the requisite preference schedules and transformation curves.

More important, however, the discussion makes only passing reference to the essential process of pure research by virtue of which most of the particular applications of the experiment stations have been made possible (*e.g.*, the genetic basis of hybrid seed corn), and the highly important process of mechanical invention and adaptation for the most part carried on in private hands, which has been chiefly responsible for the mechanization of agriculture. The fact that these processes cannot be reduced to marginal-cost-vs.-marginal-product curves should not lead to their neglect in a description of the process of economic development. Though not readily quantifiable, they are certainly subject to empirical study.

Having considered the long-term demand and supply aspects of agriculture, Schultz turns to the questions, "What particular circumstances give rise

to the process of economic development? Why does this process occur so unevenly, more especially, why does it by-pass entire communities within an economy, say within a country having well-established internal trade and migration?" These questions remain largely unanswered, but the tentative conclusion is advanced that the disparate rates of growth can chiefly be explained in terms of differences in location, which turns out to be not a matter of physical distances, but of access to alternative economic opportunities. While this factor is undoubtedly significant, one wonders at the omission of reference to differences in availability of suitable techniques from one crop region to another, and at the ready dismissal of the influence of social institutions on the rates of introduction of new techniques and adjustments. Again, the latter can be defined in quite specific terms, although their effects are not subject to precise mensuration, *e.g.*, in the South; slavery (and its successors, sharecropping and racial discrimination), plantation agriculture, the crop-lien credit system, and the discouragement of immigration, among others. A theory which is applicable to the underdeveloped countries of the world cannot avoid dealing with factors of this type.

In Part II the author provides data concerning the underlying causes of economic instability in agriculture. Instability is explained in terms of large and abrupt shifts over short intervals in the demand and supply schedules, both of which are subject to relatively low price elasticities. On the supply side, the inputs for agriculture as a whole are shown to be remarkably stable, and the fluctuations in supply are therefore attributed chiefly to variations in yield resulting from weather conditions. These variations are analyzed by regions and products. In considering the effect which producer decisions may have on supply during the time between harvests, Schultz cites the interesting case of a backward-sloping supply schedule during famine periods in countries such as India, where an increase in food prices results in a reduction of supply because farmers are enabled to consume more of their own product. In such cases the operation of the price system cannot be depended upon to correct the maldistribution, as the early medieval advocates of price control in the western world long ago showed that they well understood.

Part III presents a variety of proposals for dealing with problems of uneven economic development and agricultural instability. In this brief review it is impossible to comment on these in detail, but it should be remarked that the section abounds in richness of suggestion. Despite the criticisms which have been made, the book as a whole merits study by others than those concerned principally with agricultural problems because of its application of empirical method, the boldness of its hypotheses, and its flashes of speculative insight into the process of economic evolution.

Labor

The Harvest Labor Market in California. By LLOYD H. FISHER. (Cambridge: Harvard University Press. London: Oxford University Press. 1953. Pp. viii, 183. $4.50.)

The market for casual labor in agriculture presents many vexing problems, intellectual and social. Professor Fisher has revealed them fully in this penetrating analysis. The book begins with an economic theory of the harvest labor market. It then traces the history of labor contracting in California agriculture, and outlines its present status. The concluding chapters deal with wage-fixing by employers associations and the government.

Fisher's sympathies were clearly with the farm laborer. However, this did not prevent him from understanding thoroughly the motives and functions of growers and labor contractors. This ability to portray vividly a situation that has often been tragic and sometimes violent without creating any villains is one mark of the true social scientist.

Although Fisher was a professor of political science, he has employed economic analysis extensively, expertly, and at times originally in this work. The few flaws in his economics are all minor. For example, he assumes (p. 82) that "ideal" conditions of atomistic competition preclude a formal market organization such as an exchange; it would be more nearly correct to say that they require one.

Fisher's convincing explanations of the origins of various piecework pay practices will be of value to labor economists. Such practices are more easily understood in the simple harvest situation than in more complex industrial situations. His analysis of the demand for harvest larbor is an ingenious extension of the theory of the firm to an unusual situation.

Students of culture and of trade unions will be particularly interested in the discussion of the differences in the rôle of the labor contractor in different ethnic groups. According to Fisher, the Japanese or Filipino contractor performs functions close to those of a union leader; the Mexican, Negro, or native white contractor is a petty entrepreneur who acts as an agent for the grower.

It is in the analysis of the rôle of government that Fisher's interest in political processes comes to the fore. Growers dominated the administrative machinery for setting wage ceilings on agricultural labor during World War II, and Fisher's discussion shows deep concern over the domination of a public body by an interested group. Yet, bad though this may be in principle, it is not clear that it produced bad policy in this case. An economist might have called into question goals of government policy that seem here to be accepted at face value. Growers were reluctant to set wage ceilings for fear that labor supplies might be jeopardized; worker representation would surely have reinforced this reluctance. The neglected interest must then be that of the consumer; yet consumers as a group may have had more to gain from large harvests than from low wages. In other cases production has been

impaired by wage ceilings for low-paid, arduous work during periods of labor shortage.

The central problem of the book is that of providing an adequate work force for the intense labor demands of the harvest, demands that are often concentrated in a brief period of time, and at the same time offering to the worker some reasonable continuity of employment and a decent annual income. Related to this are a host of subsidiary problems: housing for migrant workers, schooling for their children, protection against the occasional dishonest or irresponsible contractor who recruits labor and fails to provide work, or who defaults on obligations to the worker. The problems of immigration from Mexico, legal and illegal, are also closely related. Although the book reviews the solutions to these problems that have been advanced by others, it espouses none. A trade union, in Fisher's opinion, would be more nearly able to decasualize labor and perform the functions of the contractor than would a government employment service. Yet he recognized that reform either by unions or government would be resisted bitterly and with almost certain success by growers and contractors. It is in part political realism or even pessimism that distinguishes Fisher's position from that of such reformers as Carey McWilliams.

The style of this book is clear, concise, and colorful. Quotations from newspapers, committee hearings, and similar sources are used to good advantage.

Though *The Harvest Labor Market in California* is narrow in scope, it is exceedingly broad in its treatment of its subject. Though it is analytical, it is nevertheless human. It is impossible to read it without feeling the greatness of the loss to social science caused by Lloyd Fisher's untimely death.

ALBERT REES

University of Chicago

Strikes: A Study in Industrial Conflict—with Special Reference to British Experience Between 1911 and 1947. By K. G. J. C. KNOWLES. (New York: Philosophical Library. 1952. Pp. xiv, 330. $8.75.)

Mr. Knowles' two-part study is a meticulous statistical analysis of strikes in England over a 37-year period, prefaced by a qualitative description of the institutional developments affecting industrial militancy and hence, strike statistics.

The book's central theme is the changed character of British strikes, the shift from prolonged industrial battles of the past to today's lightning "protest demonstrations," and the reasons for this transformation. The trade union movement itself rather than political and legal restrictions is seen by the author as the principal cause of strike de-emphasis. While official union policy has shifted to reliance upon negotiating machinery and "responsible dependence" upon government, the strike has become a method of rebellion by the distrustful rank-and-file members against both the peace-oriented union and a benefit-providing government. Increasingly since the General Strike of

1926, and almost exclusively since the out-break of World War II strikes have been unofficial—unsupported by the union organizations. The author suggests that the unofficial strike may be "an essential safety-valve under a system of national collective bargaining," while the official strike will languish "as long as political methods of achieving social and economic objectives" are available. This theme's treatment reveals a nostalgia for the less complicated days of old-fashioned strike action prior to the development of elaborate peace machinery and politically oriented unionism. This attitude is probably related to the author's expressed sympathy for rank-and-file worker expression which is cramped in an era of union and government bureaucracy.

After providing in Part A a description of the impact on employer-employee relations of unions, employer associations and government, the author, a member of the Oxford Institute of Statistics, demonstrates the usefulness, as well as the limitations, of strike statistics. In Part B the causes and effects of strike activity are assessed carefully, presenting available governmental statistics for the years 1911 to 1947 in a series of excellent graphs and clearly labeled tables. Standardized "strike-proneness" ratios for major British industries and geographical regions are constructed. The author concludes that regional influences on striking are "to a large extent industrial causes in disguise."

Although a statistician, Knowles emphasizes the underlying social and psychological "imponderables" as causes of strikes, while discounting the immediate causes which are subject to classification and quantification. (". . . in practice, the cause may be no more than the last straw.") In evaluating the "tenuous" statistical evidence on the effects of strikes, the results in terms of wage increases secured and production lost are found to be small. Again Knowles selects a factor which "cannot be measured at all," the general economic context within which strikes occur, as of major importance in determining actual strike costs. Throughout the study the author's acute awareness of the limited validity of statistical interpretation of strike behavior is evident, while acknowledgment (and use) is made of the contributions of the social sciences. Frequent references to American studies, such as Florence Peterson's *Strikes in the United States, 1880-1936*, and Warner and Low's *The Social System of the Modern Factory*, relate the British evidence to American experience.

Numerous sections of the five chapters which comprise the book are short essays which may be read separately with profit. Such varied subjects as the General Strike of 1926, women in strikes, fatigue and frustration, organized strike-breaking, breakaway unions and joint union-management committees are explored with pertinent reference to the contributions of other writers. Greater integration of these essays would have been desirable; their discrete excellence is not a substitute for relational significance. Although the large number of footnotes may slow reading pace, they provide such an array of historical illustrations, interesting sidelights and on occasion droll humor that eye excursions to the bottom of each page soon become habitual. Appendices within chapters and at the end of the book present more detailed information

on the statistical procedures utilized. Suggestions for improving the collectior and classification of strike statistics are made in the final appendix. Th extensive footnote citations of both American and British sources serve in liet of a bibliography.

Knowles proves well his contention that statistical description, despit its limitations has "an essential place in the systematizing of empirica knowledge." Intuitive generalizations about the trends in British strikes ir recent decades—their frequency, size, duration, officially listed causes an results—are rendered unnecessary by the availability of this quantifie experience data. However, the inability of statistical analysis to plumb th ultimate motivations and attitudes of workers and employers in conflic situations constitutes a challenge, well recognized by the author, to the disci plines which may contribute to a science of human behavior.

This study of industrial conflict in transition is a happy blend of statistica exactitude and imaginative social insights which American students of th labor movement and social groups should find of value, whatever the natur of their specialized discipline or methodological preference.

Réglementation des paiements avec étranger—Suisse. Suppl. 6. (Basle: Bank for Internat. Settlements. 1953. Pp. var.)

Report to Congress on the Mutual Security Program for the six months ended June 30, 1953. (Washington: Supt. Docs. 1953. Pp. v, 61. 35c.)

The revival of monetary policy: text and charts of an informal discussion at the eighth annual meeting of the Board of Governors of the International Monetary Fund. (Washington: Internat. Monetary Fund. 1953. Pp. 16.)

Study of factors limiting American private foreign investments: summary of preliminary findings and recommendations. (Washington: Office Internat. Trade, Dept. of Commerce. 1953. Pp. 39.)

Technical assistance for productivity: a guide to services available to industry, labor and agriculture abroad. (Washington: Mutual Security Agency. 1953. Pp. 35.)

Third report on co-ordination of oil refinery expansion in the OEEC countries. (New York: Columbia Univ. Press. 1953. Pp. 85. $2.)

Trade Agreements Extension Act of 1953. Hearings before the House Committee on Ways and Means, 83d Cong., 1st sess., May 1-19, 1953. (Washington: Supt. Docs. 1953. Pp. 2028.)

U.S. technical and economic assistance in the Far East: a part of the Mutual Security Program for fiscal year 1954. (Washington: Mutual Security Agency. 1953. Pp. 70.)

World-wide enforcement of strategic trade controls. Mutual Defense Assistance Control Act of 1951 (the Battle Act). 3d report to Cong. (Washington: Supt. Docs. 1953. Pp. vi, 96. 30c.)

Business Administration

BAKER, H. G. *Rich's of Atlanta—the story of a store—since 1867.* (Atlanta: Div. of Research, Atlanta Div., Univ. of Georgia. 1953. Pp. xviii, 411. $7.50.)

BAKKEN, H. H. *Theory of markets and marketing.* (Madison, Wis.: Mimir Pub. Co. 1953. Pp. xi, 362.)

BOWEN, H. R. *Social responsibilities of the businessman.* Ser. on ethics and econ. of Society of the Federal Council of Churches. (New York: Harper. 1953. Pp. xii, 276. $4.)

"This book is concerned with the role of businessmen in an economy of free enterprise. Its purpose is to explore the implications of the much-discussed 'concept of social responsibility' as applied to businessmen. It proceeds from the assumption that the several hundred largest business firms are vital centers of power and decision, and actions of these firms touch the lives of the American people at many points. The basic questions considered are: What responsibilities to society may businessmen reasonably be expected to assume? What tangible benefits might result if the concern of many businessmen about the social implications of their work were spread widely throughout the business structure? What steps might be taken, practically, to give greater effect to the broader social aspects of business decisions? What are other basic ethical issues facing American businessmen today?" (From the preface).

COWAN, D. R. G., ed. *Annual Marketing Research Conference: contributed papers May 8-9, 1953.* Michigan bus. papers no. 27. (Ann Arbor: Univ. of Michigan, School of Bus. Administration. 1953. Pp. vi, 116. $2.)

CULEY, R. T. and BAUER, R. D. M. *Auditing.* (Cincinnati, Ohio: South-western Pub. Co. 1953. Pp. x, 598.)

NOTES

Announcements of Retirements

The practice of publishing annually a list of members of the profession retiring from active teaching at the close of each academic year will be continued. Such list will be published in the March 1954 issue. Department heads of colleges and universities will be asked to submit the names of members of their staffs who will become emeritus in June 1954. Individuals who wish to be included in the list are asked to advise department heads or the editor of the *Review* not later than January 4, 1954.

Publications

A volume on *The Teaching of Economics,* sponsored by the International Economic Association and UNESCO is to be published in April 1954. The volume consists of reports and papers on this subject presented at the Talloires Conference, August 27-30, 1951. Members of the American Economic Association will be able to purchase the volume, through the Secretary, at a reduced price. Further particulars will be provided in the March number of the *Review.*

Economic Abstracts

The Library of the Economic Information Service of the Netherlands Ministry of Economic Affairs in collaboration with the Library of the Netherlands School of Economics and the Library of the Ministry of Social Affairs is publishing a periodical entitled *Economic Abstracts*—a semi-monthly review of abstracts on economics, finance, trade and industry, management and labour. Annual subscription rate outside of the Netherlands is Guilders 27.50. The periodical may be obtained through booksellers or from the publisher, Martinus Nijhoff, The Hague, Netherlands. Abstracts published in the form of documentary cards, as described in the September 1952 number of this *Review,* continue to be available on a subscription basis.

Research Fellowships and Grants

The Social Science Research Council has announced fellowships and grants of two distinct types to be offered in 1954: (1) Those designed exclusively to afford training in research in social science and designated as *Research Training Fellowships* and *Undergraduate Research Stipends;* (2) Those designed to aid scholars of established competence in the execution of their research, namely, the *Faculty Research Fellowships* and *Grants-in-Aid of Research.* The latter awards are not available to students working for degrees.

Inquiries should be addressed to the Social Science Research Council, 726 Jackson Place, N.W., Washington 6, D.C., and applications, on forms provided by the Council, must be filed not later than January 4, 1954.

It is to be noted that *Area Research Training Fellowships* and *Travel Grants for Area Research* are no longer available.

Deaths

Arthur A. Bright, Jr., died May 14, 1953.

Theodore T. Bullock, professor of economics and business law in the College of Business Administration of the University of Nebraska, died September 22, 1953.

Eli F. Heckscher, honorary member of the American Economic Association, died December 23, 1952.

Maurice C. Latta, assistant professor of economics in the College of Business Administration of the University of Nebraska, died September 12, 1953.

Nicholas W. Rodin, research associate in the Russian Economics Project and lecturer in McCoy College, Johns Hopkins University, died October 7, 1953.

O. M. W. Sprague, professor emeritus of Harvard University, died May 24, 1953.

Donald H. Wallace, director of the Woodrow Wilson School of Public and International Affairs, Princeton University, died September 19, 1953.

Retirements

J. I. Falconer, head of the department of agricultural economics and rural sociology Ohio State University, June, 1953.

Clarence Heer, Kenan professor of economics, University of North Carolina.

Solomon S. Huebner, as emeritus professor of insurance, the Wharton School, University of Pennsylvania, July, 1953.

D. D. Lescohier, as emeritus professor of economics, University of Wisconsin.

George A. MacFarland, as emeritus professor of accounting, the Wharton School, University of Pennsylvania, July, 1953.

William H. Spencer, Hobart W. Williams distinguished service professor of law and business, School of Business, University of Chicago, September, 1953.

John B. Woosley, Kenan professor of finance, University of North Carolina.

Appointments and Resignations

Edwin Young has been appointed chairman of the department of economics at the University of Wisconsin.

Alois L. Zaremba, of Ohio State University, has been appointed lecturer in economics at Western Reserve University.

The American Economic Review

VOL. XLIII, NO. 5 PART II DECEMBER, 195

HANDBOOK OF THE AMERICAN ECONOMIC ASSOCIATION

Edited by the Secretary

CONTENTS

PRINTED BY GEORGE BANTA PUBLISHING COMPANY

Publication Office: 450 Ahnaip Street, Menasha, Wisconsin

Executive Office: American Economic Association, Northwestern University, Evanston, Illinois

Inquiries and other communications regarding membership, meetings, and the general affairs of the Association, as well as orders for publications, should be addressed to Dr. James Washington Bell, Secretary of the American Economic Association, Northwestern University, Evanston, Illinois.

Entered at the post office at Menasha, Wisconsin, as second class matter. Acceptance for mailing at special rate of postage under the provisions of Sec. 34–40 Par. (D) provided for in the Act of February 28, 1925, embodied in paragraph 4, section 412, P. L. and R., authorized September 13, 1928.

The *American Economic Review* is published five times a year, in March, May, June, September, and December, and is sent to all members of the American Economic Association as one of the privileges of membership, $5.00 of the annual membership dues of $6.00 being in payment of a year's subscription to the publication. Printed in U.S.A.

PRICE, $2.00

PURPOSE OF THE AMERICAN ECONOMIC ASSOCIATION

The American Economic Association is an organization composed of per sons interested in the study of political economy or the economic phases o political and social questions. As may be seen by examining the list of mem bers printed in this supplement, not only are all the universities and the mos prominent colleges in the country represented in the Association by thei teachers of economics and related subjects, but a large number of member come from among businessmen, journalists, lawyers, men in public life, an others interested in economic principles, or, more often, in their application to social life. The Association has, besides, a growing representation in foreig countries.

The annual meetings, usually held during the Christmas holidays, are ar ranged as forums for the discussion of scientific questions and problems o social and economic policy. They give opportunity for contact and genera understanding among teachers, students, and businessmen interested in suc questions. The meetings aim to counteract any tendency to particularism which geographical separation and diverse interests might otherwise foster

The publications of the Association were begun in March, 1886. The firs series of eleven volumes was completed by a general index in 1897. The secon series, comprising two volumes, was published in 1897–99, and in additio thereto the Association issued during 1896–99 four volumes of *Economi Studies*. In 1900 a third series of quarterly publications was begun with th Papers and Proceedings of the Twelfth Annual Meeting, and was continue through 1910. *The Economic Bulletin*, issued quarterly and devoted to bibli ography and current notes, was also published by the Association during th three years, 1908, 1909, and 1910.

In 1911 the Association began publishing the *American Economic Review* a quarterly journal devoted to articles on economic subjects, reviews, ab stracts of articles in current journals, and a classified bibliography of eco nomic publications. During the forty-one years of its existence, the *Review* has made a place for itself among the scientific journals of the country.

The American Economic Association is the organ of no party, sect, o institution. It has no creed. Persons of all shades of economic opinion ar found among its members, and widely different views are given a hearing i its annual meetings and through its publications.

With the exception of the Editor of the *American Economic Review* and th Secretary-Treasurer, the officers of the Association receive no remuneration for their services. The Association's entire receipts are expended for the edit ing, printing, and circulation of the publications and for the annual meetings.

CHARTER AND BYLAWS OF THE AMERICAN ECONOMIC ASSOCIATION

The charter of incorporation of the American Economic Association, incorporated in the District of Columbia, February 3, 1923, provides as follows:

I. The name or title by which the society shall be known is the American Economic Association.

II. The time for which it is organized is perpetual.

III. The particular business and object of the society are as follows:

1. The encouragement of economic research, especially the historical study of the actual conditions of industrial life;

2. The issue of publications on economic subjects;

3. The encouragement of perfect freedom of economic discussion. The Association as such will take no partisan attitude, nor will it commit its members to any position on practical economic questions.

IV. The number of its trustees for the first year of its existence shall be fourteen.

The following bylaws have been adopted for the government of the Association:

I. Membership

1. Any person interested in economic inquiry may, on the nomination of a member, be enrolled in this Association.

2. There shall be six classes of members other than honorary: members paying an annual fee of $6.00; family members (two or more living at the same address, second membership without subscription to the publications of the Association) paying an annual fee of $1.00; junior members (available to registered students for three consecutive years only) paying an annual fee of $3.00; subscribing members paying an annual fee of $10.00; contributing members paying an annual fee of $25.00 or more; and life members comprising those members who contribute $100.00 or more in a single payment. Life members shall be exempt from annual fees. Members shall have each year the privilege of designating the class of membership they choose for that year.[1]

3. Foreign economists of distinction, not exceeding twenty-five in number, may be elected honorary members of the Association.

4. Every member is entitled to receive, as they appear, all reports and publications of the Association.

II. Trustees

The trustees of this Association shall not be less than fourteen or more than fifteen in number, and the Board of Trustees shall be known as the Executive Committee. The Board of Trustees shall be composed of the persons elected as the Executive Committee at the time and place and in the manner set forth in the following bylaw providing for the election of officers.

III. Officers[2]

1. The Association shall have the following officers who shall be elective officers: a President, two Vice-Presidents, six elected members of the Executive Committee. The terms of office of the President and Vice-President shall each be one year. The terms of office of the six elected members of the Executive Committee shall each be three years, two of the six terms of the six elected members of the Executive Committee to expire each year. Each regular term of office shall coincide with a calendar year or a multiple thereof.

[1] As amended at the December 28, 1940, and the December 29, 1948 annual meetings.

[2] Amendments as adopted at the annual meeting, December 29, 1933, and by mail ballot announced at the Business Meeting, January 26, 1946.

2. As early in each year as practicable, the President of the Association shall appoint Nominating Committee, consisting of a past officer,[1] as chairman, and not less than five oth members of the Association. The names of the Committee shall be published in the March June issue of the AMERICAN ECONOMIC REVIEW with an invitation to the general membersh that suggestions of nominees for the various offices be sent to the chairman of the Committe The Nominating Committee shall be instructed to present to the Secretary of the Associatic on or before September 1 of each year a nominee for the presidency and two or more nomin tions for each elective office to be filled, the nominees being members of the Association. Tl candidate for president shall be selected by an electoral college consisting of the members the Nominating and the Executive Committees. Space shall be provided on the ballot for tl individual voter's alternative choice.[3]

3. Elective officers shall be chosen through elections to be held during the last three[1] montl of the term of office of his predecessor. Each member shall be given the opportunity to vote t mail. The results of the election shall be certified and announced by the Secretary at the annu business meeting.

4. The Association shall have the following officers who shall be appointed by the Executi Committee: a Secretary, a Treasurer, a Managing Editor, and a Counsel. The terms of offi of each of these officers shall be three calendar years. The Managing Editor shall, with tl advice and consent of the Executive Committee, appoint members to an Editorial Board assist him. The President may, at his discretion and with the advice and consent of the Exec tive Committee, appoint a Program Committee.

5. The Executive Committee shall consist of the President, the Vice-Presidents, the Secretar the Treasurer, the Managing Editor, the three ex-Presidents who have last held office, and s elected members, provided that the Secretary, the Treasurer, and the Managing Editor sha not be entitled to vote in the Committee's meetings.

IV. DUTIES OF OFFICERS

1. The President of the Association shall preside at all meetings of the Association and the Executive Committee, and in consultation with the Program Committee, shall prepare tl programs for the annual meetings. In case of his disability, his duties shall devolve upon tl Vice-Presidents in the order of their election, upon the Secretary, and upon the Treasurer.

2. The Secretary shall keep the records of the Association and perform such other duties the Executive Committee may assign to him.

3. The Treasurer shall receive and have the custody of the funds of the Association, subje to the rules of the Executive Committee.

4. The Executive Committee shall have the control and management of the funds of tl corporation. It may fill vacancies in the list of officers, and may adopt any rules or regulatio for the conduct of its business not inconsistent with this constitution or with rules adopted the annual meeting. It shall act as a committee on time and place of meetings and perform su other duties as the Association shall delegate to it. A quorum shall consist of five members.

5. The Editorial Board shall have charge of the publications of the Association. The Mana ing Editor shall be ex officio member and chairman of the Editorial Board.

6. The office of the corporation for legal purposes shall be at the office of the Counsel in tl District of Columbia, and legal process against the corporation may be served on said Couns

V. ANNUAL MEETING

The annual meeting of this corporation shall be held at such time and place as may be d termined by the Executive Committee. Notice of such time and place shall be given by public tion in the regular journal of the corporation, now known as the AMERICAN ECONOMIC REVIE at least ten days prior to such meeting. The first annual meeting shall be held at Providenc

[3] As amended at the December 29, 1938, and December 29, 1941, annual meetings.

EDITORIAL NOTE

The present edition of the handbook of the Association contains the follow
ing information: lists of officers, charter and bylaws of the Association, a
alphabetical list of members and a geographical list of members and sub
scribers (with addresses), as of April 15, 1953, and statistical summaries.

This 1953 *Handbook* differs in form from the "who's who" directories. A
revised directory is planned for publication in 1955. In the meantime, sinc
our membership list has been subject to so many changes, it was considere
desirable to bring out a handbook at this time.

The information in the appendix brings up to date some of the tables con
tained in previous directories and handbooks and also adds some new ma
terial. The detail is shown in the table of contents.

The increasing amount and variety of inquiries received by this offic
prompt the Editor to include in this note the following summary of publishe
sources of information concerning the activities of the Association:

1. *The American Economic Review*—a quarterly publication containin
main articles, book reviews, bibliographical and personal notes, records c
special investigations by individuals and public commissions.

2. *The Papers and Proceedings* of the annual meetings of the Associatio
(edited by the Secretary)—main papers, round table summaries, togethe
with reports of the Secretary, the Treasurer, the Editor, Finance Committee
Auditor, standing and special committees, minutes of the Executive Com
mittee and of the business meetings. The appendix contains a cumulative lis
of the contents of the *Papers and Proceedings* from 1911 and of the publica
tions of the Association since 1886.

3. *The Handbook* and *Directory*—the former biennial handbook has sinc
1938 been published irregularly, in two forms; namely, the handbook, con
taining names and addresses of members, together with the year from whic
their continuous membership dates, and the directory, which is a specialize
"who's who" of members, with classification according to subject-matte
fields. Directories appeared in 1938, 1942, and 1948. The 1905 handboo
contained very brief biographical sketches of members.

4. *Information Booklet*—describing the purposes, organization, and activi
ties of the Association, designed to answer inquiries from prospective mem
bers. Sent free upon request.

JAMES WASHINGTON BELL, *Secretary*

ROSTERS OF COMMITTEE MEMBERS AND EDITORIAL BOARDS

NOMINATING COMMITTEE*

1949–53

1949	Simeon E. Leland, Chairman James K. Hall Margaret G. Reid Lloyd G. Reynolds Edward C. Simmons Wolfgang F. Stolper
1950	Calvin B. Hoover, Chairman Harold R. Bowen Carter Goodrich Elizabeth E. Hoyt Alfred C. Neal Jacob Viner
1951	Howard S. Ellis, Chairman Karl R. Bopp George A. Elliott Charles P. Kindleberger Lloyd A. Metzler William H. Nicholls
1952	Frank H. Knight, Chairman Anne Bezanson George H. Hildebrand Frank A. Knox Donald H. Wallace Clair Wilcox
1953	John H. Williams, Chairman M. M. Bober Edward S. Shaw George W. Stocking George W. Taylor Willard L. Thorp

* For list of members 1934–48, see page 305 of the 1948 *Directory*.

COMMITTEE ON ELECTIONS*

1934–52

1934	Frederick S. Deibler, Chairman Ernest L. Bogart Morris A. Copeland
1935	Chester W. Wright, Chairman Reuben Cahn
1936	Ivan Wright, Chairman John Higson Cover
1937	Melchior Palyi, Chairman Frank P. Breckinridge
1938	Donald R. Cowan, Chairman Albert G. Hart Lloyd W. Mints
1939	Reuben D. Cahn, Chairman Frederick W. Mueller, Jr.
1940	Henry C. Simons, Jr., Chairman Elmo P. Hohman
1941	Morton Bodfish, Chairman Melchior Palyi
1942	Leverett S. Lyon, Chairman Simeon E. Leland
1943	Garfield V. Cox, Chairman Arthur R. Tebbutt
1944	John W. Boatwright, Chairman Earl J. Hamilton
1945	John K. Langum, Chairman Henry B. Arthur
1946	John H. Wills, Chairman Walter E. Hoadley, Jr.
1947	Ernest A. Johnson, Chairman Charles W. Anrod
1948	J. Roy Blough, Chairman Ernst A. Dauer
1949	Lloyd A. Metzler, Chairman Frank W. Fetter
1950	Walter A. Weisskopf, Chairman Louis A. Keller
1951	Harry G. Guthmann, Chairman Robert T. Glidden
1952	Donald S. Warning, Chairman Harold W. Torgerson

* The Secretary is ex officio member of the Committee on Elections. For 1935, this was Frederick S. Deibler; from 1936 on, James Washington Bell.

PROGRAM COMMITTEE*

ANNUAL MEETINGS

1936–55

NOTE: A tabulation of "Statistics of Annual Meetings" from 1885 to 1910 may be fou in the papers and discussions on the occasion of the twenty-fifth anniversary of the Associati published in the "Third Series" of the publications of the Association (Vol. XI, 1910, No. pages 92–93). This tabulation gives not only the date and place of meeting but also indica main subjects discussed and the number of members of the Association. The list of cities which annual meetings have been held 1910 through 1935 may be found on page 306 of 1948 *Directory.*

The following list includes estimates of registration. These figures are very rough, but th give a general idea of how many members of the American Economic Association attend meetings and of the total attendance of all the affiliated associations. Some figures are estima of attendance, which includes students and those not registering, and other figures are p registrations.

Year	*Place*	*Local Arrangements Chairman or Representative*	*A.E.A.*	*Total*

Western Economic Association

Officers, 1953

President, M. M. Stockwell, University of California (Los Angeles). *Vice-President*, C. E. Maser, Oregon State College. *Secretary-Treasurer*, John Pagani, University of Utah. *Editor*, F. L. Kidner, University of California (Berkeley).

The Western Economic Association (formerly the Pacific Coast Economic Association) was established in 1922 largely through the efforts of Alfred C. Schmitt, Edwin C. Robbins, Stephen I. Miller and Eliot Jones. The first meeting was held in Portland, Oregon. Membership is of two kinds: (1) institutional members, originally confined to accredited universities and colleges west of the Rocky Mountains, but now changed to include any educational institution approved by the Executive Committee, west of the Rockies; (2) individual members, who may be any person interested in the theory, principles and problems of economics and business. In addition to the professional economists, many Pacific Coast businessmen are members.

One of the principles of the W.E.A. is to devote approximately one-third or more of each annual conference to problems of the Pacific Slope; another is to co-operate with the efforts of the Social Science Research Council.

The membership of the Association as of September 1, 1952 was 409. Institutional dues are $10.00 and $5.00, depending upon size of the institution; individual membership is $3.00 yearly. The principal publication is the annual proceedings.

Past Presidents

1922	Alfred C. Schmitt, Oregon State College	1938	James K. Hall, University of Washington
1923	Eliot Jones, Stanford University	1939	Richard B. Heflebower, Washington State College
1924	Rockwell D. Hunt, University of Southern California	1940	Arthur G. Coons, Claremont Colleges

1932	Shirley J. Coon, University of Washington	1950	Dilworth Walker, University of Utah
1933	Clement Akerman, Reed College	1951	John A. Guthrie, State College of Washington
1934	Reid L. McClung, University of Southern California	1952	Oliver P. Wheeler, Federal Reserve Bank of San Francisco
1935	W. L. Wanlass, Utah State College		
1936	Kenneth Duncan, Pomona College		
1937	John B. Canning, Stanford University		

Metropolitan Economic Association

Officers, 1953–54

President, Lawrence Chenault, Hunter College. *Vice-President*, Harry Malisoff, Brooklyn College. *Secretary*, Aurelia Toyer, New York University. *Treasurer*, Robert D. Leiter, City College.

The Metropolitan Economic Association was formed in the spring of 1949 when a group of

college teachers of economics in the metropolitan New York area met to organize a confere on the teaching of the basic course in economics. The conference became the Metropoli Economic Association. The object of the Association is to encourage and organize the express of diverse views on matters of interest to academic and nonacademic economists. Meetings held four times yearly for the purpose of such discussions.

Membership is open to those who teach economics in colleges, to nonacademic professic economists, and to graduate students majoring in economics. Dues are $1.00 annually. membership of the Association as of May, 1953, was 150.

Past Presidents

1950–51 Broadus Mitchell, Rutgers University
1951–52 Charles Hessian, Brooklyn College
1952–53 David H. Colin, New York U versity

CENTRAL NEW YORK ECONOMICS CONFERENCE

Officers, Fall Meeting, 1953

President, Raymond de Roover, Wells College. *Secretary-Treasurer*, Dorothy Watson, W College.

The Central New York Economics Conference was organized in 1948. The purpose of Conference is to enable its members to discuss mutual problems of teaching and to excha views on current economic issues.

The Conference meets twice a year and is financed by a small registration fee paid at the t of each meeting. The meeting place of the Conference is rotated among the various colleges universities of its members.

Past Presidents

1948 Spring Meeting—Wilfrid Crook, Colgate University
Fall Meeting—William Kessler, Colgate University
1949 Spring Meeting—Archibald M. McIsaac, Syracuse University
Fall Meeting—William E. Dunkman, University of Rochester
1950 Spring Meeting—William W. Bennett, Union College
Fall Meeting—N. Arnold Tolles, Cornell University
1951 Spring Meeting—Kirk R. Petshek, Colgate University
Fall Meeting—G. Ralph Smith, Harpur College
1952 Spring Meeting—Theo Suranyi-Unger, Syracuse University
Fall Meeting—Ralph C. Epstein, University of Buffalo
1953 Spring Meeting—William E. Dunkman, University of Rochester

ECONOMIC HISTORY ASSOCIATION

Officers, 1952–54

President, Edward C. Kirkland, Bowdoin College. *Vice-Presidents*, Alexander Gerschenk Harvard University, Robert L. Reynolds, University of Wisconsin. *Secretary*, Ralph Hidy, New York University. *Treasurer*, Herman E. Krooss, New York University. *B of Trustees*, The Officers of the Association, the Editor of the *Journal*, Arthur Bin University of Pennsylvania, W. Thomas Easterbrook, University of Toronto, Solo Fabricant, New York University, John G. B. Hutchins, Cornell University, Arthu Peterson (representing the Agricultural History Society), Henrietta M. Larson (repres ing the Business Historical Society), and *Past Presidents*, Anne Bezanson, Universit Pennsylvania, Herbert Heaton, University of Minnesota, Earl J. Hamilton, Universit Chicago. *Editor*, Thomas C. Cochran, University of Pennsylvania. *Advisory Editor*, Sl ard B. Clough, Columbia University. *Associate Editors*, Miriam Hussey, Universit Pennsylvania, Daniel Thorner, University of Pennsylvania.

The Economic History Association was founded in December, 1940. It is open to all hist ans, statisticians, economists, and businessmen who find profit from historical investigati It publishes semiannually the *Journal of Economic History*. EXHIBIT 2

THE PROFESSION OF ECONOMIST

The brief statement which follows represents an initial effort to describe what an economist is and what he does and what may be expected by those who contemplate the study of economics as a preparation for a career.

The attempt to formulate an explanation of "economist" as a profession was originally prompted by a request to the Association from the office of the National Roster of Scientific and Specialized Personnel (now a branch of the United States Employment Service of the Department of Labor). The first draft submitted by the Secretary was pitched at too high a professional level and was redrafted by the National Roster staff to meet the needs of those seeking vocational information. This version did not meet our approval and we were given an opportunity to make further criticisms and suggestions. The description in its present form owes its character largely to the revisions made by a committee consisting of F. W. Fetter, Fritz Machlup, H. S. Ellis, and your Secretary.

DESCRIPTION OF THE PROFESSION OF ECONOMIST

Occupational Summary

Economists study the whole process through which man makes a living and satisfies his wants for food, shelter, service or amusement, and the conditions favoring or hampering his economic development. This includes where, how and what man produces, how goods and services are distributed and paid for. They study the organization of industries; the labor supply and its use; the commercial banking and credit structure and government finance, both local and national; international trade and how it is financed; the national income and wealth, its production and distribution; the growth and shifts in population; standards of living; the use and conservation of land and natural resources. The objective of economists is to point out what policies and programs in industry or government will aid in the development of an industry or will facilitate the growth of trade and raise the individual's standard of living. Many economists are college teachers, others are in the employ of industry or government serving as statisticians, research analysts or advisors on economic policies and programs.

Economists study in their basic training all branches of economic theory. Some specialize in one or more branches since many of these subjects tend to overlap or merge.

Major Branches

1. *Economic Theory:* The economist specializing in economic theory is familiar with the history of economic institutions and practices, and makes a comparative and analytical examination of past and present systems of economic organization (e.g. feudalism, state socialism, capitalism, etc.) and of the systems of thought underlying these organizations.
2. *Money, Banking, and Finance:* Economists specializing in this branch study the nature and functions of money and banks, the means by which banks create purchasing power, and devices used to regulate amount of bank lending. They study forms of credit and credit instruments, and the relationship of money purchasing power to levels of economic activity. The fiscal economist studies the ways in which government is financed and public funds are spent; the effects of taxation and spending upon business activity as a whole; and plans a distribution of taxes equitable for all elements of the population.
3. *Industry:* The economist specializing in industry studies forms of business organizations, with arrangements for the production and marketing of goods and services and thus studies costs and prices, private investment policies, wholesale or retail trade, business trends, regulation by government of industrial monopoly and industry generally. The economist may specialize in one one or more specific industries, either non-manufacturing, such as forestry, or construction; or manufacturing, such as food, textiles, lumber, paper, iron, steel, petroleum or rubber.

In the transportation and public utilities

industries he studies rates, valuations, traffic or use of service, and materials as they affect railways; aviation; water transportation; electric power and gas; highway, bus and truck transportation; radio and radio broadcasting; and wire communications. He also studies the effects of government regulation, consolidations and monopoly, ownership and operation in these industries.

Economists in this field attempt to explain why the national output of goods and services is subject to fluctuations, and to recommend measures for assuring a higher and more stable level of output and employment. They investigate the influence of private investment (production of new plant and equipment), of government spending and taxing, of monopolies, and of wage policies, upon the level of employment. As a guide to future policy, they make estimates of the size of the national output which our country is capable of producing.

4. *International Trade:* The economist specializing in international trade studies the factors determining the movement of goods among nations; trade restrictions, including tariffs, quotas, and exchange controls; the operation of foreign exchange; international investment and the problems of international capital transfer.
5. *Agricultural Economics:* The agricultural economist studies the economic aspects of agriculture, and its relationship to other fields of economics, in particular transportation, money and banking, and international trade. He studies farm management, crop estimating, agricultural credit, marketing of farm production, and commodity exchanges, and their relation to crop production and prices. He also studies the relationship between the agricultural production and income and the rest of the economy, its tax structure, labor supply, tariff policies and other aspects.
6. *Labor Economics:* The labor economist studies factors affecting the supply, demand, organization, and well-being of labor. He studies wages and hours; industrial versus craft unions; management policies; pensions, insurance, and other welfare matters; labor legislation; labor disputes; conciliation, arbitration; and the effect of labor policies on industry and the national economy.
7. *Socio-Economics:* The economist specializing in this branch studies broad developments as they affect the economic welfare of the country. This includes such subjects as population growth and movements; national income by social group; the occupational distribution of people; the conservation and use of such natural resources as minerals, water power and land; and regional planning.

Functional Activities

The economist may specialize in one or in a combination of any of the following functional activities:

1. Teaching—at the college or university level. He usually but not always engages in part-time research.
2. Research—he conducts research on a full-time basis in government, in business and industrial establishments, in banks, in labor unions and at private research foundations.
3. Management or Administration of industry or government.
4. Technical editing and writing of books, magazines, pamphlets, and newspaper articles.
5. Consulting and advisory work for governments, business and financial institutions, and investors.

Professional Affiliations and Civil Service Status

Membership in a national or local professional organization is no criterion of professional status since such membership is open to anyone interested in the objectives or activities of the society. Most economists, however, are affiliated with one or more professional societies.

In the Federal Civil Service and in many state or local civil service jurisdictions, a professional job classification or a rating on a civil service register as economist generally indicates the professional status of the economist. Economists may also be classified by civil service as social science analyst, or labor market analyst, labor relations specialist, tax expert.

Educational Qualifications

The professional economist usually possesses an M.A. or Ph.D. in economics. Such a degree is generally required for advancement in colleges and universities. For the higher levels in the government service and in industry where the Ph.D. is not shown, the equivalent in professional experience and graduate work is usually required. Junior positions in the Federal service are, however, open to those with a bachelor's degree and a major in economics.

Related Occupations

(a) High school teachers of economics who may possess a bachelor's degree in economics are classified as *teachers, high school* rather than as professional economists.
(b) Journalists and radio news commentators usually are interested in economic affairs and express opinions upon economic issues, but they ordinarily are not classified as economists.
(c) Bankers, bank cashiers, and related banking, insurance and finance occupations are classified under managerial occupations.
(d) Home economists are classified as such.
(e) Those engaged in rural rehabilitation, and farm planning and demonstration are usually not classified as economists.

Sources of Employment

Economists are employed for the most part as college and university teachers, and in research and administrative capacities in government and business (banks, investment houses, railroads, public utilities, manufacturing firms). They find employment also with labor unions and private research institutes. Some are self-employed as consultants.
